Acknowledgements

First of all, I would like to thank *Prof. Dr. Christof Sparr* for giving me the opportunity to investigate so many interesting projects and for all the support throughout these four years of PhD. For all the knowledge and experience I gained theoretically and practically and for all the discussions and challenges especially during group seminars, I'm very grateful.

I thank *Prof. Dr. Florian Seebeck* for kindly accepting to be my second supervisor and for all the relevant suggestions during our yearly meetings. I would like to thank *Prof. Dr. Michal Juriček* for being my external expert in the co-examination of this thesis as well as *Prof. Dr. Oliver S. Wenger* for chairing the defense.

I am very grateful for all the people who helped proof-read my thesis: *Daniel Moser, Dr. Anja Stampfli, Zlatko Jončev, Dragan Miladinov and Alessandro Castrogiovanni and Markus Jakobi*. Many thanks to the whole *Sparr Group* for the great mood, interesting discussion during lunch breaks, and for all the nice moments in and outside of the lab.

I am particularly thankful to *Markus Jakobi* for collaborating on the acridinium salts project. I would like to thank my incredible student *Romaric Corsi* for his hard work and joyful mood during a particular hot summer in the lab.

Many thanks go to the outstanding analytical service especially *PD Dr. Daniel Häussinger* for the NMR puzzles and *Dr. Michael Pfeffer* for his efficiency with my peculiar samples. For an exceptional technical support, I'm grateful for the *Werkstatt-Team* and *Oliver Ilg*.

Special thanks go to our great secretary, *Marina Mambelli-Johnson* for the personal advices, the little cakes left in the breakroom, for all the nice discussions and of course for an incredible administrative work.

I would also like to thank the other people of the department who helped me throughout these four years by technical or mental support especially *Anja, Raj, Pierre, and Ronan*. Thank you for all the nice aperos and barbecues.

Je voudrais maintenant prendre le temps de remercier mes amis. Ces années à Bâle m'ont permis de faire d'incroyables rencontres et de tisser de belles amitiés. Je voudrais remercier *Zlatko* pour son inspiration, sa folie et son soutien. Je tiens surtout à exprimer ma plus grande gratitude à mon frère de cœur, *Alessandro* pour son soutien indéfectible tout au long de cette

thèse, pour ses incroyables histoires, pour son aide précieuse et pour tous ces moments partagés, merci.

J'aimerais rendre hommage à mes amis en dehors du labo, *Yasmina* et *Hani* pour toutes ces belles soirées et ce beau voyage, et bien sûr pour m'avoir autant épaulé. J'aimerais aussi remercier mes amis Parisiens qui m'ont toujours soutenu : *Marianne, Laura, Alexandra et Hind*. Un grand merci à ma compatriote de toujours, à ma Nono pour être là, même après nos études et pour nos week-ends entre Bâle et Genève.

Je n'aurai bien entendu rien pu accomplir sans l'aide, le soutien et l'amour de *mes parents*. J'aimerais remercier *ma mère*, cette héroïne, qui m'a toujours suivi avec enthousiasme et confiance dans chacune de mes aventures. Elle est ma plus belle source d'inspiration et cette thèse lui est grandement dédiée.

Enfin, je voudrais remercier ma plus belle rencontre durant ces quatre ans, mon compagnon, *Matthias*, qui a fait preuve d'une patience au-delà de l'imaginable pour me supporter pendant ces derniers mois d'écriture. Merci d'avoir pris si bien soin de moi, merci pour les délicieux diners, pour l'amour et pour l'aide que tu m'as apporté. Je n'y serais jamais arrivée sans toi. Vielen Dank.

Abstract

Stereoselective organocatalyzed transformations involving rotationally restricted systems

Stereoselective organocatalyzed reactions are powerful synthetic tools complementary to transition metal-catalyzed transformations that allow access to a large variety of chiral scaffolds with stereogenic centers, axes or planes. Due to their low toxicity and ready availability, small molecule catalysts represent thus a more sustainable alternative for the synthesis of complex structures.

Herein we investigated an enantiospecific electrophilic substitution catalyzed by *ortho*-substituted anilines through the formation of atropisomeric enamine intermediates. Using an enantiopure α -fluorinated aldehyde as a substrate, several anilines bearing bulky *ortho*-substituents were tested to selectively catalyze the addition of an electrophile to form a quaternary stereocenter with retention or inversion of configuration.

Multi-axis systems with rotationally restricted bonds are topologically well-defined motifs and valuable chiral scaffolds with diverse applications from catalysis to medicinal chemistry. However, synthetic pathways to these compounds as well as studies about their rotational behavior remain scarce. Therefore, we reported the enantioselective synthesis of rotationally restricted aromatic amides displaying three stereogenic axes. Catalyzed by a chiral tetrazole derived proline, the anilides were obtained with an e.r. up to 87:13 and a *cis/trans* ratio of 1:3. An exhaustive study was conducted to identify the 3D structures of the major compounds and to deepen our understanding regarding their rotational behavior

Due to their peculiar handle-shaped structure imparting them a stereogenic plane, cyclophanes have always been a fascination for chemists around the world. Widely spread among natural products and bioactive compounds, they also find application in nanotechnologies and material sciences. If multiple synthetic strategy to access such macrocycles have already been described, the development of organocatalyzed transformation to obtain enantiopure cyclophanes is severely limited. Hence, we explored the use of the enantioselective arene forming aldol condensation developed in our group to achieve the synthesis of enantiopure paracyclophanes with an anthracene core and fifteen methylene groups on the side chain.

Synthesis of acridinium salts and their application in photoredox catalysis

The continuous development of photocatalytic methods motivates the design of organic catalysts towards a more sustainable approach, in order to complement the frequently used and precious polypyridyl transition metal complexes. However, this rational design is often hampered by the mechanistic complexity and low modularity of the catalyst structure. Herein, a scalable synthesis of symmetric acridinium dyes was reported. Optimized reaction

conditions and purification methods allowed to prepare these catalysts on multi-gram scale, using a double halogen-metal exchanged as a key step.

A thorough photophysical study of a diverging photocatalytic pathway drove the design and fully modular synthesis of asymmetric acridinium catalysts. A combination of halogen-metal exchange with directed *ortho*-metalation allowed to generate a wide panel of dyes with fine-tuned photophysical and photochemical properties.

Given the high degradation observed for several dyes during a photocatalytic reaction, the design of a new generation of photostable acridinium salts was tackled. Symmetric photocatalyst with carbazole moieties and asymmetric ones with a methoxy group on one side and a diphenylamino group on the other side of the core were thus synthesized

Finally, application in photoredox deuterations and *trans*-stilbene isomerization were described. The symmetric acridinium catalysts, prepared on multi-gram scale, allowed the deuteration of a pharmaceutically relevant scaffold in high yield and selectivity. The asymmetric ones gave 84% of *cis*-stilbene through a TTET (triplet-triplet energy transfer).

1 INTRODUCTION

1.1 ROTATIONALLY RESTRICTED SYSTEMS

1.1.1 Enantiospecific reactions through the formation of rotationally restricted enolates

Enantiospecific reactions are powerful tools for the stereoselective synthesis of drugs^[1] and natural products.^[2] Throughout these transformations, an enantiopure starting material is controlling the absolute configuration of the product as exemplified by the S_N2 reaction. Starting from an enantiopure compound, the attack of a nucleophile leads to a Walden inversion in an absolute stereocontrol (Scheme 1, top). However, in regard to S_N1 reactions, enantiopure starting materials with sp^3 -hybridized stereogenic centers get trigonalized during the transformation which is known to lead to racemic mixtures. Therefore, S_N1 reactions represent a challenging enantiospecific reaction to perform (Scheme 1, bottom).^[3],^[4]

Scheme 1: Enantiospecific S_N2 with Walden inversion (top) and general mechanism for α -addition (bottom).

In 1981, Seebach and Wasmuth took serendipitously a first step into solving this question with an interesting discovery while investigating the β -alkylation of diethyl malate (Scheme 2, top).^{[5],[3]} They reasoned that upon addition of the electrophile following the dilithiation of the substrate, the β -alkylated product would be formed (Scheme 2, top). However, after

deprotonation with lithium diethylamide of the substrate and alkylation with iodomethane, they observed two distinct products. The desired β -alkylated compound was received in moderate yield (55%) but an unexpected side product generated by the α -alkylation could also be isolated in 15% yield with 60% ee (Scheme 2, bottom). This discovery led to different hypothesis regarding the mechanism behind this outcome. The side product could be the result of mixed aggregate of the intermediates. Or, the stereogenic axis arising from a non-co-planar orientation of the enolate and imine moieties (along the C_{α} -N bond) could direct the absolute configuration of the side product. Even though the first hypothesis was confirmed later, this discovery set the path to a new concept for enantiospecific S_N1 type reactions: rotationally restricted enolates.^[6]

Scheme 2: β -alkylation of diethyl malate (top) and discovery of enantiospecific α -alkylation through the formation of rotationally restricted enolates.

Therefore, Seebach and coworkers designed an innovative approach to achieve this idea (Scheme 3).^[6] Starting from a chiral compound with two functional groups but only one stereogenic center, the reaction with an aldehyde auxiliary would form an acetal, creating thus a second stereocenter. After the trigonalization of the original stereocenter, the temporary one would control diastereoselectively the addition step. Finally, a cleavage of the

acetal would lead to the enantiopure product either with inversion or retention of configuration.

Scheme 3: Mechanistic hypothesis for the enantiospecific S_N1 type reactions.

This strategy was then widely applied for the synthesis of α -alkylated amino-acids and more specifically proline (Scheme 4, top).^[7] Pivaldehyde was chosen as a cleavable auxiliary for its high diastereoselectivity and efficiency for acetalization without side product formation during the alkylation step (due to the bulkiness and inertia of the *t*-Bu group). Moreover, this reagent has a low boiling point (74°C) which makes it easily removable after cleavage. The addition of the pivaldehyde to L-proline thus led to the formation of a bicyclic acetal as a single diastereomer. Upon deprotonation with LDA, the intermediate with a newly created stereocenter directs the subsequent addition of allyl bromide which generates, after cleavage of the auxiliary, (*S*)- α -allylproline with retention of configuration in good yields (87%). Thereafter, this method was frequently applied in the total synthesis of natural products (Scheme 4, bottom).^{[8], [4]}

**(-)-Brevianamide****(+)-Lactacystin****(S)-Desferrithiocin**

Scheme 4: α -allylation of L-proline through enantiopure enolate intermediate (top) and natural products synthesized using this method (bottom).

Ten years later, Fuji and Kawabata took a step further by designing enantiopure ketones which upon deprotonation generate a rotationally restricted enolate.^[9] The stereogenic axis is then the element which is controlling the absolute configuration during the alkylation step compared to the previously designed stereogenic center control (Scheme 5). This approach allowed to avoid the use of an auxiliary and could provide the α -alkylated product in moderate yield (48%) and good ee (66%). Better results were achieved when moving on to amides which through an intermediate with a hindered rotation about the C-N bond ($\tau_{1/2} = 22\text{h}$ at -78°C) led to the product in excellent yield (91%) and selectivity (81%).^{[10], [11]}

Scheme 5: Enantiospecific methylation through rotationally restricted enolates.

Kawabata could also extend this method to intermediates with rotationally restricted C-O bond to perform an enantiospecific five-membered cyclization of alkyl aryl ethers (Scheme 6).^[12] The bulkiness of the *ortho* substituent is crucial in this transformation to maintain a rotational barrier of the enolate around 11-12 kcal.mol⁻¹. Although the intermediate is short-lived, an efficient induction of enantioselectivity (84–99%) could be achieved with retention of absolute configuration in moderate to good yields (20–82%).

Scheme 6: Enantiospecific cyclization through rotationally restricted enolate.

Broadening this concept, Penso, Lupi and coworkers reported an elegant enantiospecific intramolecular α -arylation through the formation of a rotationally restricted enolate (Scheme 7).^[13] Starting from an alanine derivative, the deprotonation leads to a conformer where the *t*-Bu group and the sulfonyl group are remote from each other giving rise to a rotationally restricted enolate. A subsequent intramolecular nucleophilic attack of the enolate on the aromatic ring generates a spiro-Meisenheimer intermediate which upon elimination of sulfur dioxide delivers the product.

Scheme 7: Synthesis of α -quaternary α -amino acids derivatives through rotationally restricted enolates (top) and proposed mechanism (bottom).

Carlier and coworkers even applied this method to enantiospecific electrophilic addition on Benzodiazepines (Scheme 8).^[14] Upon deprotonation, the starting material of (*S*) configuration known to adopt preferentially a (*M*) conformation (confirmed by X-Ray) leads to an enolate intermediate with a restricted C-N bond (barrier for racemization around 20

kcal mol^{-1}). The addition then occurs then on the concave face which places the electrophile in the pseudo-axial position and gives the product with retention of configuration. Even though this spatial arrangement seems sterically hindered, the addition on the concave face decreases torsional strains and increases imine and amide resonance.

Scheme 8: Enantiospecific electrophilic addition on Benzodiazepines through rotationally restricted enolate.

In light of these examples, it appears that rotationally restricted enolate intermediates are a powerful tool to induce enantiospecific $\text{S}_{\text{N}}1$ type reactions. This method was broadly applicable to various starting material from amino-acids to more complex structures and even drug-like molecules. The extension of this concept to rotationally restricted enamines will be discussed later in this thesis.

1.1.2 Stereoselective synthesis of atropisomers and multi-axis systems

Even though plethora of methods have been developed and reported for the synthesis of enantioenriched compounds with stereocenters, the area remains to be explored when it comes to molecules with one or multiple stereogenic axis. First experimentally discovered by Christie and Kenner in 1922^[15] and further labeled by Kuhn in 1933,^[16] atropisomers (from the Greek “a” = not and “tropos” = turn) are stereoisomers arising from a hindered rotation about a single bond (Scheme 9). Their valuable chiral scaffolds provide a broad range of topologies with various application from catalyst design to medicinal chemistry.^[17–21]

Scheme 9: Configuration of atropisomers.

Traditionally prepared by cross coupling followed by kinetic resolution, several synthetic approaches such as de novo construction of arenes, conversion of a stereodynamic system, desymmetrization and many others have been since developed to access those structurally-well defined motifs.^[22–31]

Pioneered by Bringmann, the use of a lactone bridge was one of the first innovative stereoselective functionalization of racemic biaryls (Scheme 10, top).^[32] After esterification to attach the two aromatic moieties, the cyclization through aryl coupling leads to the formation of the ester bridge. This lactone plays a key role in decreasing the rotational barrier to ensure a racemic mixture of configurationally unstable compounds. Finally, the enantioselective cleavage with chiral nucleophiles allow the formation of enantioenriched atropisomeric biaryls. This dynamic kinetic resolution (DKR) strategy granted access to the synthesis of a large variety of natural products with a stereogenic axis (Scheme 10, bottom).^[33]

Scheme 10: “Lactone concept” for the synthesis of atropisomeric biaryls (top) and natural products (bottom).

Following a biomimetic approach, atroposelective oxidative couplings catalyzed by enzymes or small molecules were also often used as a method to obtain enantioenriched natural products with a stereogenic axis.^[34–38] For instance, Shaw and coworkers employed a *t*-leucine-BINOL derived vanadium complex for a related coupling of two naphthylpyranone units in the total synthesis of (–)-virditoxin.^[39] This efficient reaction led to the tetra-*ortho* substituted biaryl intermediate with excellent diastereoselectivity (95:5) (Scheme 11).

Scheme 11: Total synthesis of (-)-Viridotoxin.

Although this strategy can be very effective, the attachment of two identical moieties severely limits its application. To circumvent this issue and access a broader scope of molecular scaffolds, atroposelective cross-couplings were further developed as reported by Buchwald in a pioneering study about the synthesis of atropisomeric phosphonates.^[40–43] In a similar process involving a bidentate ferrocenyl aminophosphine ligand, Gu and coworkers achieved an atropisomeric Suzuki cross-coupling of 2-iodo-2,3-unsaturated enones with trisubstituted aromatic boronic acids or boronic esters to obtain configurationally stable precursors of 2,2'-biphenol motifs (Scheme 12, top).^[44] In an interesting approach disclosed by Suginome and co-workers, a Suzuki cross-coupling of arylboronic acids with 1-bromo-2-naphthylphosphonates catalyzed by a chiral polymeric quinoxaline biarylphosphine (PQXphos) delivered a panel of atropisomeric biaryl phosphonates (Scheme 12, bottom).^[45] Noticeably, the selectivity can be inverted by heating the catalyst which triggers a switch of configuration regarding the helicity.

Scheme 12: Atroposelective Suzuki cross-coupling for the synthesis of arylcyclohexanones (top) and biaryl phosphonates (bottom).

As an alternative to cross-coupling, the conversion of a stereodynamic system is a powerful tool to generate atropisomers in high selectivity. Illustrated by Bressy, Bugaut, and Rodriguez, an elegant Hantzsch-type reaction allowed the atroposelective synthesis of 4-arylpyridines (Scheme 13).^[46] The enantioselective Michael addition catalyzed by a chiral thiourea derivative was followed by the condensation with an ammonium acetate salt, giving rise to 1,4-dihydropyridines. By transferring central-to-axial stereogenic information during the MnO_2 oxidation, a variety of atropisomeric 4-arylpyridine derivatives were obtained, a general scaffold comprising members with antitumor and antiviral properties.

Scheme 13: Atroposelective Hantzsch-type synthesis of 4- arylpyridines.

For scaffolds with restricted rotation about a C–N bond, Bencivenni studied a new class of succinimides, a type of compounds well-known for their antiseizure properties (Scheme 14).^[47] An atroposelective Diels–Alder reaction catalyzed by a chiral primary amine allowed the successful desymmetrization of *N*-arylmaleimides, giving rise to a large range of heteroaryls displaying three stereocenters as well as a stereogenic axis. Notably, the sterically demanding *t*-butyl substituent in the *ortho* position is fundamental for sufficiently restricting the rotation about the C–N axis.

Scheme 14: Stereoselective desymmetrization of *N*-arylmaleimides.

In order to achieve more versatility for the preparation of biaryls and non-biaryls compounds, the *de novo* construction of a rotationally restricted system was widely investigated. In a seminal atroposelective [2+2+2]-cycloaddition catalyzed by a rhodium/ H_8 -BINAP complex, Tanaka described a highly efficient synthesis of QUINAP-type phosphine oxides (Scheme 15, top).^[48] Turning to gold catalysis, Gong explored the atroposelective synthesis of boron-based

heteroaryls, a relevant scaffold in drug discovery (Scheme 15, bottom).^[49] A cycloisomerization-amination cascade reaction allowed the stereoselective construction of a variety of heteroaryls. The protecting groups on the diazene are thus responsible for the restricted rotation about the C–N bond of the corresponding hydrazide. The postulated mechanism involves an initial coordination of the Au(I) complex to the alkyne to form a vinylgold intermediate. The latter is added to the diazene, itself coordinated to a chiral gold complex, giving rise to a configurationally stable compound with a stereogenic axis.

Scheme 15: De novo synthesis of substituted QUINAPs (top) and gold-catalyzed atroposelective synthesis of amino-oxaborininol derivatives (bottom).

By using an earth-abundant metal combined with an organocatalyst, Tan developed an atroposelective synthesis of arylpyrroles, a motif largely found among natural products (Scheme 16).^[50] A Paal–Knorr reaction catalyzed by a chiral phosphoric acid, with iron(III) triflate as a Lewis acid, led to a diversity of arylpyrroles with stereogenic axes. After the formation of a key enamine intermediate, the chiral phosphoric acid catalyzes the dehydrative cyclization resulting in the formation of the atropisomer. The rotation about the C–N bond was sufficiently suppressed by the ortho substituents on the pyrrole moiety and the aryl ring.

Scheme 16: Atroposelective Paal-Knorr for the synthesis of arylpyrrole derivatives.

Towards a more biomimetic approach inspired by the biosynthesis of aromatic polyketides, our group developed a stereoselective arene-forming aldol condensation of ketoaldehydes catalyzed by a pyrrolidinyl tetrazole. This method allowed for the atropisomeric synthesis of biaryls as well as rotationally restricted aromatic amides in high yields and selectivity, under mild conditions (Scheme 17).^[51,52]

Scheme 17: Atroposelective arene forming aldol condensation for the synthesis of biaryl (top) rotationally restricted aromatic amides (bottom).

In light of its high efficiency, the atroposelective aldol condensation was extended to the synthesis of multi-axis systems. An iterative sequence of building block addition, oxidation of the diol to the corresponding ketoaldehyde, and a catalyst- or substrate-controlled stereoselective aldol condensation delivered configurationally stable oligo-1,2-naphthylenes with multiple stereogenic axes in high enantioselectivity (Scheme 18, top).^[53] This study was further used as a platform for the investigation of a catalyst-controlled atropodivergent synthesis of oligo-1,2-naphthylenes with up to four stereogenic axes (Scheme 18, bottom).^[54]

Scheme 18: stereoselective synthesis of oligo-1,2-naphthylenes (top) and stereodivergent synthesis of an atropisomeric four-axis system (bottom).

Achieving the synthesis of one of the largest multi-axis systems, Tsubaki reported the preparation of dotriacontanaphthalenes (Scheme 19, top).^[55] These optically active rod-shaped oligo-1,4-naphthalenes were assembled by sequential oxidative couplings catalyzed by Cu(II) to reach an impressive maximum of 32 units. Studying a different type of oligomers, Clayden and coworkers disclosed an investigation of the conformational behavior in solution of oligo-*m*-benzanilides and oligo-*p*-benzanilides involving three different set of stereogenic axis (Ar-CO, N-CO, Ar-N).^[56] Although a conformational control was achieved on short dimers and trimers, a mixture of conformers was obtained when extending the oligomers (Scheme 19, bottom).

Scheme 19: Atroposelective synthesis of oligo-1,4-naphthalenes (top) and conformational study of oligo-benzanilides (bottom).

Exploring a two-axis system of benzamide-like scaffolds, Miller and coworkers accomplished an elegant atropisomeric peptide-catalyzed tribromination of rotationally restricted amides (Scheme 20).^[57] This transformation produced thus four stereoisomer in an interesting partial equilibrium where one pair of diastereomer is enantioenriched at the expense of the other,

without a loss of the overall enantiomeric excess. Although the enantiomeric ratios are fluctuating, each enantiomeric pair was produced under the influence of the catalyst.

Scheme 20: Catalytic atropisomeric bromination of a two-axis benzamide.

In conclusion, various conceptually distinct methods for the stereoselective synthesis of atropisomers are emerging although the pathway to multi-axis systems remains challenging and scarce. Elegant strategies that allow the transfer of stereochemical information from substrates or readily available catalysts into important atropisomeric structures have been elaborated. With methods becoming available for their synthesis, the various types of atropisomers and multi-axis systems will find widespread applications in several research fields.

1.1.3 Cyclophanes

Cyclophanes are macrocycles constituted by one or several aromatic units connected with an aliphatic chain forming a bridge (Scheme 21). First discovered by Lüttringhaus in 1942 who baptized them “ansa-compounds” (“ansa” = handle in Latin) regarding their peculiar shape, they were referred to as “di-*p*-xylylene” by Brown and Farthing.^[58,59] Finally, the Nobel prize winner Cram suggested the name “paracyclophane” to characterize this class of compounds.^[60] Nowadays, the nomenclature of those scaffolds is influenced by two factors: the macrocyclic ring system (maximum number of noncumulative double bonds) and the connectivity of the interlinked chain (saturated or not).^[61] Furthermore, these molecules are optically active as a result of the restricted rotation about the side chain. The stereogenic plane is formed by the position of the spacer regarding the aromatic ring. Therefore, the length and rigidity of the handle as well as the size of the substituents on the ring affect directly their rotational barrier.^[62]

Scheme 21: Evolution of the nomenclature of cyclophanes.

Due to their unique structure and properties, cyclophanes have known applications in multiple fields. With the presence of phosphine groups on the aromatic core, they are valuable ligands for asymmetric catalysis (Scheme 22, top right).^[63,64] Moreover, their optical and electronical features are widely explored in nanotechnologies and material sciences

(Scheme 22, top left).^[65,66] Finally, they are broadly spread among natural products (Scheme 22, bottom).^[67–69]

Scheme 22: Applications of cyclophanes in material sciences (top left), asymmetric catalysis (top right), and natural products (bottom).

The synthesis of cyclophanes follow mainly two strategies to close the macrocycle.^[69] The de novo construction of the aromatic ring can be achieved primarily through cycloaddition (Diels Alder, [2+2+2]) or rearrangement. On the other hand, the junction of the alkyl chain offers more synthetic options such as metathesis, olefination, esterification, cross coupling, aromatic substitution, addition, rearrangement and many more.^[70–73]

Several rearrangements have been used to build the aromatic core of cyclophanes. For instance, Gleiter and coworkers reported an elegant synthesis of cyclopropanophanes (Scheme 23, top).^[74] After a tetrabromination in α -position of the diketone, a Favorskii rearrangement triggers the formation of the cyclopropane. Through a Beckman rearrangement, Uemura and coworkers accomplished the formation of a cyclophane

containing an oxazole moiety starting from an α -formylketoxime dimethyl acetal (Scheme 23, bottom).^[75]

Scheme 23: Preparation of cyclophanes through Favorskii (top) and Beckman rearrangement (bottom).

The de novo construction of the aromatic moiety was also carried out through various cycloaddition reactions as illustrated by Wulff and coworkers who achieved the synthesis of cyclophanes via a Dötz benzannulation (Scheme 24, top).^[76] Involving a Fischer carbene complex, the [3+2+1] cycloaddition generated two regioisomers in 40% and 21% yield. A famous type of cycloaddition often used is the [4+2] as described by Cossy and Meyer who reported a diastereoselective sequential Diels-Alder/retro Diels-Alder strategy for the synthesis of functionalized $[n]$ paracyclophanes (Scheme 24, bottom).^[77]

Scheme 24: Preparation of cyclophanes through *de novo* construction of the aromatic ring through benzannulation (top) and Diels-Alder (bottom).

Towards an enantioselective approach, Tanaka and coworkers applied a [2+2+2] cycloaddition to access strained dioxo[7]paracyclophanes (Scheme 25, top).^[78] Catalyzed by a Rhodium-BINAP complex, the product was obtained in moderate yield with up to 75% ee. Starting from branched triynes, Shibata and coworkers successfully achieved the synthesis of diverse cyclophanes in high yields and enantioselectivity, using a Rhodium-DUPHOS complex (Scheme 25, bottom).^[79]

Scheme 25: Preparation of cyclophanes through enantioselective rhodium catalyzed [2+2+2] cycloaddition.

For the synthesis of a natural product, Kondo and Miyake described an original Hantzsch pyridine strategy to obtain a normuscopyridine analogue (Scheme 26).^[80] An oxymercuration-oxidation sequence followed by a condensation with hydroxylamine hydrochloride delivered [11](2,6)-pyridinophane.

Scheme 26: Synthesis of a normuscopyridine analogue through Hantzsch synthesis.

Addition reactions are also widely used to close the macrocycle via the alkyl chain as illustrated by Erker and coworkers who used an intramolecular Mannich-type condensation to synthesize amino-substituted [3]ferrocenophane (Scheme 27, top).^[81] With a cascade reaction involving a Michael addition, Reißig and coworkers reported an elegant route towards benzannulated cyclodecanone derivatives (Scheme 27, middle).^[82] Taking advantage of carbonyl chemistry, Shinmyozu and coworkers described an efficient aldol condensation strategy to access hyperconjugated multibridged [3_n]cyclophanes with significant π -donating properties in almost quantitative yields (Scheme 28, bottom).^[83]

Scheme 27: Preparation of cyclophanes through mannich condensation (top), Michael addition (middle) and aldol condensation (bottom).

The extensive development of metathesis reactions opened up the synthetic strategies to the preparation of cyclophanes with higher chains and more complex structures with a larger functional group tolerance. Starting from a sugar-containing macrocycle, Murphy and Jarikote disclosed an alkyne metathesis catalyzed by $\text{Mo}(\text{CO})_6$ to obtain a glycothane (Scheme 28, top).^[70] For natural product synthesis, the ring closing metathesis (RCM) has been a method of choice for many years. Smith and coworkers illustrated this approach by completing the total synthesis of (–)-cylindrocyclophane A, an antitumoral agent originally isolated from a blue-green alga (Scheme 28, middle).^[83] The use of Schrock's catalyst delivered in high yield (78%) the dialkene intermediate which was converted to the product after reduction and deprotection. Towards the use of Ruthenium based catalysts, Kotha and Shirbhate reported a pathway to the longithorone scaffold involving a RCM catalyzed by Grubbs II (Scheme 28, bottom).^[71]

Scheme 28: Macrocyclization through alkyne metathesis (top) and ring closing metathesis (middle and bottom).

Although metathesis reactions are powerful tools to close macrocycles, coupling reactions remain one of the most widely spread methods for the synthesis of a large panel of cyclophanes. Among them, Glaser couplings are often used as a key step to ensure the junction of two terminal alkynes.^[73,84–86] As illustrated by Kotha and Waghule, a Glaser-Eglinton coupling catalyzed by Cu(II) delivered a macrocyclic bisacetylene derivative which was converted to the desired cyclophane after reduction (Scheme 29, top).^[87] Cross couplings such as Kumada, Sonogashira, Suzuki, Heck and many more are as well extensively employed because of their high reactivity and performance.^[88–92] Following this strategy, Speicher and

Colobert disclosed an atroposelective Heck coupling for the synthesis of enantiopure isoplagiochin D, a macrocyclic bioactive compound with a rotationally restricted axis (Scheme 29, bottom).^[93] With an enantiopure sulfinyl auxiliary, a complete control over the diastereoselectivity of the transformation could be achieved in good yield (98% ee for the (*aS*)-atropisomer). Finally, the sulfinyl intermediate was cleaved and converted to the natural product without erosion of selectivity.

Scheme 29: Glaser coupling (top) and atroposelective Heck coupling (bottom) for the synthesis of cyclophanes.

Towards a catalyst-controlled approach, Cai and coworkers developed an enantioselective synthesis of (–)-pterocarine and (–)-galeon, two natural products from woody plants with bioactive properties (Scheme 30).^[67] Using a chiral phase transfer catalyst, an efficient $\text{S}_{\text{N}}\text{Ar}$ cyclization led to the formation of a key diarylether intermediate in high enantioselectivity and good yield (91:9 e.r. then 99:1 after recrystallization) which was then converted to the corresponding natural products without erosion of ee.

Scheme 30: Enantioselective synthesis of (–)-pterocaraine and (–)-galeon.

In conclusion, a plethora of strategies can be used to construct cyclophane scaffolds as previously discussed. Several other strategies including C-H arylation,^[94] Friedel and Crafts,^[95,96] esterification,^[97] olefination,^[98] radical mechanism,^[99] alkylation,^[100] elimination^[101] and many more are known synthetic methods for the obtention of these macrocycles. However, stereoselective approaches to achieve the synthesis of enantiopure cyclophanes remain scarce. Later in this thesis, a strategy to access enantiopure cyclophanes will be examined.

1.2 ACRIDINIUM SALTS IN PHOTOREDOX CATALYSIS

Polypyridyl transition metal systems have been transformative for the field of photoredox catalysis with ruthenium and iridium catalysts representing particularly versatile scaffolds (Scheme 31).^[102–105] The wide range of properties due to the tunability of their ligands make them exceptionally valuable catalysts for photochemical transformations. With the development of fully organic alternatives, the area opened up towards potentially sustainable processes.^[106–108] Among them, acridinium salts pioneered by Fukuzumi^[109,110] are known to have remarkable photophysical properties, complementary to those of polypyridyl transition metal structures. Their high reduction potential in the excited state (often $E_{1/2} [P^*/P^-] > 2$ V vs. SCE) and their robustness, pH independence, and high solubility in a variety of solvents, render them valuable photocatalysts for a wide range of preparative transformations.

Scheme 31: Commonly used photoredox catalysts.

1.2.1 Synthetic strategies for the formation of acridinium salts

The design of acridinium dyes initially evolved towards an increased chemical stability. First, Fukuzumi integrated a bulky mesityl group at the C9 position to prevent nucleophilic addition that results in photobleaching.^[109] Moreover, the introduction of electron donating groups favours charge transfer by the stabilizing mesityl moiety.^[111] As a consequence, the MesMe-Acr⁺ displays unique oxidizing properties ($E_{1/2} [P^*/P^-] = +2.08$ V vs. SCE), with a suitable lifetime of the singlet and triplet excited state, which renders it a valuable catalyst for numerous photochemical reactions.^[112–115] To further overcome competitive dealkylation processes, Nicewicz developed N-arylated acridinium salts with higher chemical stability and an extended range of redox properties ($E_{1/2} [P^*/P^-] = 1.62–2.08$ V vs. SCE, Scheme 32).^[116]

Scheme 32: Representative photocatalysts reported by Nicewicz and coworkers.

A series of symmetrically substituted acridinium salts were prepared, with alkyl or methoxy substituents attached to the acridinium core. A one step synthesis featuring a triarylamine precursor in a Friedel–Crafts reaction with a benzoyl chloride derivative delivered the desired acridinium salt with a tetrasubstituted core in good yields (71–81%, Scheme 33). Recently, Nicewicz and co-workers designed an efficient synthesis of acridinium photocatalysts starting from xanthylium salts.^[117] The rapid assembly of a xanthylium dye was thereby combined with a condensation reaction with an aniline to give the corresponding acridinium salt.

Scheme 33: Synthetic strategies for acridinium salts.

Furthermore, an elegant strategy consisting of an oxidative Ugi-type reaction for the synthesis of a novel class of imideacridinium salts has been developed by Mancheño and Alemán (Scheme 34).^[118] Starting from N-substituted acridanes, a coppercatalysed oxidation takes place at the C9 position to give a cationic intermediate that reacts with the isocyanide. After addition of the in situ formed benzoate, the intermediate is concomitantly rearranged in an Ugi-type fashion to produce C9-substituted imide-acridanes. A subsequent aromatization by hydride abstraction carried out by tritylperchlorate delivered the desired acridinium salt. Photophysical and photoredox studies of these catalysts have been conducted.^[119] Direct applications in photoredox catalysis were subsequently demonstrated with a suitable activity in several benchmarking transformation including anti-Markovnikov hydrofunctionalization of alkenes and a dehydrogenative lactonization of alkenes and a dehydrogenative lactonization.

Scheme 34: Ugi reaction for the synthesis of acridinium salts and their application.

The evolution of the synthesis of acridinium salts towards more modular approaches allowed the diversification of their scaffold in order to tune their photophysical properties. In order to access this range of acridinium salts, individual strategies were employed for a modular synthetic preparation. For the synthesis of symmetrical acridinium salts, such as diamino derivatives, a 1,5-bifunctional organomagnesium reagent was added to a variety of carboxylic acid esters to provide a broad range of acridinium derivatives (Scheme 35, top).^[120] The synthesis of 1,8-dimethoxy substituted acridinium dyes was achieved through a double directed ortho-metalation (DoM) to generate the 1,5-organodilithium reagent that was engaged in a direct ester to heterocycle transformation with variation of the carboxylic acid esters (Scheme 35, middle).^[121] This approach also enabled the synthesis of atropisomeric acridinium salts with a 1,8-dimethoxy-peri-substitution and 9-naphthyl moiety (Scheme 35, bottom).^[122] After reduction of the racemic acridinium, the enantiomers of the leuco-form with a diastereomeric ratio of 97 : 3 were separated by HPLC and reoxidized by chloranil to give the two atropisomerically pure compounds. These compounds display a remarkable configurational stability with bond-rotational barriers of $\Delta G^\ddagger_{298\text{K}} = 124 \text{ kJ.mol}^{-1}$ and $\Delta G^\ddagger_{298\text{K}} = 127 \text{ kJ.mol}^{-1}$ respectively.

Scheme 35: 1,5-bifunctional organomagnesium reagent for the synthesis of unfunctionalized and diamino acridinium dyes (top), double directed ortho-metalation (dDoM) for the synthesis of 1,8-dimethoxy substituted acridinium salts (middle) and synthesis of atropisomeric acridinium salts (bottom).

1.2.2 Acridinium salts as organophotoredox catalysts

A rapidly growing number of chemical transformations employs acridinium salts as catalysts.^[123–126] Photooxidations, polar radical crossover cycloaddition reactions, C–H functionalization, crosscoupling and cross-dehydrogenative reactions, are merely selected recent examples of the use of acridinium salts in photoredox catalysis.^[127–133] For instance, an acyl radical generation for the synthesis of asymmetric ketones was described by Fagnoni and co-workers (Scheme 36, top).^[134] Starting from readily prepared acylsilanes, the oxidation to the corresponding radical cation by Fukuzumi's catalyst led to the aliphatic acyl radical after loss of the TMS group. The addition to a Michael acceptor followed by reduction and protonation delivered a variety of asymmetric ketones. Recently, Glorius and co-workers disclosed a carbonyl olefin cross-metathesis catalysed by an acridinium salt derived from Nicewicz's 3,6-di-*tert*-butyl acridinium catalyst (Scheme 36, bottom).^[135] 1,3-Diols are thereby

generated from aldehydes and alkenes upon visible-light irradiation that subsequently undergo acid-promoted Grob-type fragmentations. After the elimination of acetone, the cross-metathesis product is thereby formed.

Scheme 36: Photocatalyzed acylation of Michael acceptors (top) and carbonyl olefin cross metathesis for the synthesis of disubstituted *trans* alkenes (bottom).

Using a cascade of C–H and C–C bond cleavage steps, the group of Leonori achieved an intriguing remote functionalization of nitriles and ketones induced by the photoexcited Mes-Acr-Me⁺ catalyst (Scheme 37).^[136] The key step of this transformation lies in the formation of an iminyl radical arising from the SET oxidation and deprotonation of a carboxylic acid containing cyclic oxime. For instance, a stepwise sequence of an abnormal Beckmann fragmentation and a fluorination gives access to a broad range of distal fluorinated nitriles. This strategy could also be applied to the synthesis of *g*-fluorinated and chlorinated ketones. After SET oxidation of a linear oxime, a 1,5-hydrogen abstraction provides a nucleophilic radical that reacts with *N*-chlorosuccinimide or selectfluor to deliver the targeted compounds.

Scheme 37: Remote fluorination *via* iminyl radicals.

A photocatalyzed three-component carbofluorination for the synthesis of α -fluoro- α -amino acid derivatives has been developed by Molander and co-workers (Scheme 38, top).^[137] Upon irradiation of the Mes-Acr-Me⁺ catalyst, an alkyltrifluoroborate reagent is oxidized to give an alkyl radical that adds to the dehydroalanine to generate an α -amino radical intermediate, which reacts with selectfluor to provide the α -fluoro- α -amino acids. The Nicewicz group furthermore investigated an organophotoredox catalysed C–H fluorination of arenes with ¹⁸F (Scheme 38, bottom).^[138] Using the 9-mesityl-3,6-di-*t*-butyl-10-phenylacridinium salt as a photooxidant, TEMPO as a redox co-mediator and caesium fluoride combined with tetrabutylammonium bisulfate to generate TBAF *in situ*, the ¹⁸F-fluorination of a wide range of arenes, heterocycles and even bioactive compounds was enabled. Their approach was expanded to radiofluorinations for PET imaging applications in diagnosis and pharmacological studies.

Scheme 38: Photocatalyzed synthesis of α -fluoro α -amino acids (top) and direct ¹⁸F-fluorination of arenes (bottom).

Several direct photoredox catalysed $\text{C}(\text{sp}^2)\text{--H}$ functionalization reactions induced by a dual catalytic cobalt/Mes-Acr-Me⁺ combination were explored by the group of Lei.^[139,140] Among them an oxidative phosphorylation of arenes for the synthesis of valuable molecular scaffold is described (Scheme 39, top).^[141] The key step of this reaction is the SET oxidation of the arene to give a radical cation that reacts with the trialkylated phosphite. The resulting intermediate is then oxidized to a cationic intermediate which is subsequently deprotonated. By loss of an alkyl moiety, a wide range of aryl phosphonate products were obtained, even allowing the late stage functionalization of druglike compounds. Extending the application of their dual catalytic cobalt/ acridinium salt process, the same group also performed a photooxidative [4+2] annulation between aromatic ketimine derivatives and styrenes (Scheme 39, bottom).^[142,143] The SET oxidation of the alkene substrate by the excited Mes-Acr-Me⁺ catalyst thereby produces a radical cation that reacts with the nucleophilic aromatic ketimine to give a stable benzylic radical intermediate. A subsequent sequence consisting of a cyclization, oxidation and deprotonation allows to obtain highly substituted 3,4-dihydroisoquinolines with excellent trans diastereoselectivity.

Scheme 39: Photooxidative phosphonylation of arenes (top) and photooxidative [4+2] annulation for the synthesis of 3,4-dihydroisoquinoline derivatives.

The group of Kanai investigated a different type of dual catalytic palladium/acridinium systems for the catalytic dehydrogenation of N-heterocycles under visible light irradiation at ambient temperature (Scheme 40).^[144] For tetrahydronaphthalenes, a thiophosphoric imide organocatalyst was added as a third component, allowing in this catalytic process the formation of hydrogen gas under mild conditions.

Scheme 40: Catalytic dehydrogenation of N-heterocycles (top) and tetrahydronaphthalene derivatives (bottom).

Exploiting the properties of the Mes-Acr-Me⁺, Rueping and co-workers reported a cross-coupling of allylic C(sp³)-H bonds with aryl- and vinylbromides, using a combination of nickel and an acridinium photocatalyst (Scheme 41, top).^{[120][145]} After the oxidative addition of aryl- or vinylbromide to the nickel, a triplet-triplet energy transfer was proposed to take place between the excited acridinium salt and the nickel species. Cleavage of the halogen-metal bond then generates the radical bromide, which abstracts a hydrogen from the alkene to form an allylic radical compound. The reaction with the Ni intermediate then undergoes a reductive elimination to release the allylarene or corresponding 1,4-dienes. Acridinium salts are not limited to visible light-induced catalysis but can also be used as organocatalyst based on their ground state redox properties. Taking advantage of those properties, Ooi and co-workers designed an interesting acridinium betaine catalyst that enables PCET (proton-coupled electron transfer) and applied it to the oxidative dimerization of oxindoles under air (Scheme 41, bottom).^[146] The 9-mesityl acridinium moiety acts as the redox active unit whereas the phenoxide represents the substrate activation site. Using this catalyst, a successful homodimerization of 3-aryl oxindoles could be achieved.

Scheme 41: Ni-dual catalytic cross coupling for allylic arylation (top) and dimerization of 3-aryloxindoles catalyzed by an acridinium betaine (bottom).

In conclusion, a growing library of acridinium catalysts has been developed and utilized for various visible-light photocatalytic processes. If several strategies were disclosed for the design and synthesis of highly oxidative acridinium salts, only a few allowed to reach lower excited states redox potentials similar to those of polypyridyl transition metal systems. A more modular approach providing tuneable redox properties is thus needed to achieve a suitable range of photosynthetic applications and will be discussed later in this thesis.

2 RESULTS AND DISCUSSION

2.1 STEREOSELECTIVE ORGANOCATALYZED TRANSFORMATIONS INVOLVING ROTATIONALLY RESTRICTED SYSTEMS

2.1.1 Enantiospecific electrophilic substitution through the formation of atropisomeric enamines

Enantiospecific reactions are powerful tools to generate quaternary centers, pioneered by Seebach in 1981^[147]. Starting from an enantiopure compound, an auxiliary (generally an aldehyde) is added to form an acetal as a single diastereomer. A subsequent deprotonation at the original stereocenter generates an enantiopure intermediate which can be used to direct the electrophilic addition to selectively form a new quaternary center. Finally, the cleavage of the auxiliary releases the product with either retention or inversion of configuration (Scheme 42, top). Following this concept, Kawabata used innovative rotationally restricted enolates as intermediates to direct selectively the electrophilic addition. This strategy successfully led to the synthesis of various chiral compounds including cyclic amino-acids and ether derivatives (Scheme 42, bottom).^[12,148–152] Therefore, we reasoned that such a process might be applicable to a wider range of substrates by using an organocatalyst which would give an intermediate possessing a stereogenic axis.

Scheme 42: Principle of enantiospecific electrophilic addition (top) and enantiospecific synthesis of bicyclic compounds with a quaternary stereocenter (bottom).

Inspired by the use of anilines as organocatalysts in epoxidation reactions reported by Pikho and coworkers (Scheme 43, top),^[153] we envisioned an organocatalyzed process based on the formation of an enamine intermediate with a stereogenic axis (Scheme 43, bottom). Starting from an enantiopure fluorinated aldehyde, the double *ortho*-substituted aniline would undergo a condensation with the substrate to give a rotationally restricted enamine intermediate, which would direct the electrophilic addition. Finally, hydrolysis of this

compound would generate a product with a quaternary stereocenter with either retention or inversion of configuration

Scheme 43: Pikho's epoxidation (top) and enantiospecific synthesis of quaternary stereocenter through rotationally restricted enamines (bottom).

We started our studies with the enantioselective synthesis of (*S*)-2-fluoro-3-phenylpropan-1-ol reported by Jørgensen and coworkers (Scheme 44, top).^[154] For the analysis of this reaction by chiral HPLC, an acetylation step was required prior to the measurements. An excellent e.r. of 98:2 of the derivatized product was determined, which is in high agreement with the literature data (93 % *ee* reported).^[154] We then proceeded to test the robustness of this selectivity by submitting the alcohol to a sequence of subsequent oxidation, reduction and finally acetylation in order to verify the influence of these reactions on the enantiomeric ratio (Scheme 44, bottom). To our satisfaction, the selectivity remained unscathed with an e.r. of 99:1.

Scheme 44: Enantioselective synthesis of *S*-2-fluoro-3-phenylpropan-1-ol and its acetyl derivative (top) and oxidation/reduction/acetylation (bottom).

Following this first experiment, we were curious to investigate the impact of adding anilines to the reaction, forming the hypothesized chiral enamine prior to reduction. To do so, aliquots of oxidized **2** were taken and stirred with either *o*-*t*-Bu-*N*-methyl-aniline or *N*-methylaniline respectively at RT for 24 hours (Scheme 45). The results were subsequently analyzed to the reduction/acetylation sequence. Given a significantly decreased enantioenrichment when using the *N*-methylaniline (e.r. = 78:22) compared to the *o*-*t*-Bu-*N*-methyl-aniline (e.r. = 93:7), the formation of an enamine intermediate influencing the selectivity was considered.

Scheme 45: Influence of anilines on the enantiospecific protonation of the enamine with stereogenic axis.

In a further experiment, we attempted to isolate the enamine intermediate in a stoichiometric experiment by condensing the aldehyde with *o*-*t*-Bu-aniline. The imine formation was confirmed by NMR analysis but no enamine product could be isolated. Presumably the enamine is not stable to slightly acidic or aqueous conditions, as proven by quenching the

reaction mixture by either water or acetic acid. A reduction using NaBH₄ was then performed to study the amine derivative however, after purification the compound could not be obtained. With the *o*-*t*-Bu-*N*-methyl-aniline, only starting material was observed regardless of the addition of acetic acid (Scheme 46).

Scheme 46: Enamine synthesis.

We continued our investigations by screening suitable electrophiles to perform an enantiospecific substitution (Scheme 47). A variety of electrophilic compounds was investigated using the conditions described in scheme 45. However, only NBS and NCS yielded the desired product with 50% and 100% conversion respectively after 24 h.

[a] Reaction performed with 100 μmol of **2**; [b] Conversion determined by NMR.

Scheme 47: Screening of electrophiles for the enantiospecific addition to the enamine with stereogenic axis.

Selecting NCS as the electrophile, we decided to pursue our inquiry by measuring the enantiomeric ratio using the reduction/acetylation sequence. However, following the reduction the compound could not be isolated. We therefore investigated other strategies. A first approach involving the derivatization of the aldehyde was envisaged. An aliquot of the reaction mixture was added to a solution of Brady's reagent (2,4-dinitrophenylhydrazine). However, the hydrazine adduct could not be purified for analysis. Another pathway utilizing a Pinnick-Lindgren oxidation followed by an esterification was then selected. This method allowed us to measure an e.r. of 48:52 for the desired compound (Scheme 48).

Scheme 48: Derivatization of the aldehyde.

Having the conditions in hand to analyze the enantiomeric ratio, we then proceeded to screen different substituted anilines as organocatalysts for the α -chlorination of enantiopure aldehydes. A trend became apparent, indicating that only the anilines with an EDG were able to convert the aldehyde (Table 1). In the presence of anilines bearing an EWG the reaction did not yield any product (Scheme 49). Moreover, longer reaction times and lower conversion were observed among the di-*ortho*-substituted anilines compared to their mono substituted analogues (see cat **33** and **38**). Finally, all the anilines tested led to a racemic product.

Scheme 49: Screening of anilines with EWG.

In light of these results, we considered shielding one side of the enamine intermediate through the use of secondary anilines. Accordingly, we selected the catalysts which gave the best conversion in the chlorination and prepared their corresponding benzylated derivatives. Applying the conditions of Murphy and coworkers^[155] using ZnCl_2 and NaCNBH_3 , several secondary anilines were synthesized for investigation in further screening (Scheme 50).

[a] Reaction performed with 5.33 mmol of substrate; [b] Isolated yields.

Scheme 50: Benzylation of primary anilines.

In addition to the newly synthesized anilines, three indolines were also screened (Table 2). TFA (40 mol%) was added to the reaction mixture to activate the aldehyde and to increase the conversion of the more sterically hindered catalysts. A blank reaction using catalytic amount of TFA showed as expected only starting material after 16 h. The results demonstrated that benzylated anilines with the addition of TFA generate overall a good conversion however the use of indolines did not yield any product. Interestingly, an ee of 10% was reached when using catalyst **61** despite the conversion being one of the lowest.

Table 2: Screening of secondary anilines.

Encouraged by the success of catalyst **61**, we moved to more attentively examine the role of solvents and chlorinating agents (Table 3). Catalyst **69**, which gave excellent conversion with NCS, was used with reagents **73–76**. However, these reactions resulted in very low conversion or did not yield any product. Catalyst **61**, which produced the best result in terms of enantioselectivity (10% ee), was further investigated in different solvents. While the conversion was significantly enhanced while using Et₂O (Table 3, entry 9), the use of any other solvent produced a racemic compound.

Table 3: Screening of solvents and chlorinating agents.

The absence of selectivity drove us to envisage an increase of the enamine intermediate's rotational barrier by placing a bulkier substituent in the *ortho*-position. Inspired by the

scaffold of the Jørgensen catalyst, ^[154] a synthetic route to a new *ortho*-substituted aniline was designed. Starting from methyl anthranilate, a benzyl group was first installed to convert the primary aniline using the method described above. ^[155] An excess of phenylmagnesium bromide in THF allowed for introduction of the two phenyl groups. Finally, the protection of the alcohol with TMSOTf delivered the desired catalyst **79** (Scheme 51). This newly synthesized aniline was immediately tested in the chlorination reaction using the conditions described in Scheme 45. The results show a conversion lower than 10% despite the use of TFA, likely due to the bulkiness of the substituents in *ortho*-position. However, only racemic compound was observed.

[a] Reaction performed with 100 μmol of **2**; [b] Conversion determined by NMR; [c] The e. r. was determined by HPLC on a chiral stationary phase.

Scheme 51: Design of a new *ortho*-substituted aniline **52** for organocatalysis.

Considering this outcome, we turned to another class of substrates to resume our investigations. Amino alcohol derivatives were our first choice because of their abundance as enantiopure material. Thus, we started our study with L-glycinol and L-phenylalaninol which were first protected using $(\text{Boc})_2\text{O}$ in good yields (respectively 59 and 88%). With the substrate in hand, we carried on with the investigation of a suitable electrophile for our desired transformation (Scheme 52). Surprisingly, only the chlorinating agent **75** led to full conversion. NFSI (*N*-fluorobenzenesulfonimide) showed a partial conversion of 50% while the other electrophiles tested did not yield any product. Following the chlorination, the reduction of the aldehyde was performed in order to measure the e. r. after acetylation. However, the alcohol decomposed during purification.

[a] Reaction performed with 100 μmol of **80**; [b] Conversion determined by NMR

Scheme 52: Screening of electrophiles.

In conclusion, we attempted to design an enantiospecific electrophilic addition involving rotationally restricted enamine intermediates by using *ortho*-substituted anilines as

organocatalysts. Chlorination reactions proved to be the most effective using NCS or compound **75**. Anilines bearing EDG appeared to be suitable catalysts for this transformation. Despite our efforts to increase the rotational barrier of the enamine intermediate (going from primary to secondary anilines, installing bulkier substituents in *ortho*-position), we did not achieve any significant selectivity (10% ee).

2.1.2 Enantioselective synthesis of multi-axis systems: atropisomeric aromatic amides

With their structurally well-defined scaffolds, multiaxis systems have always been a fascination for the study of rotational behaviors.^[55,156,157] However, due to their molecular complexity, only a few catalyst-controlled stereoselective methods to prepare them have been developed.^[54,57] Taking a strong interest in non biaryl systems and more particularly atropisomeric anilines, a challenging synthesis of a three-axis aromatic amide system was tackled. This topic has been previously explored by our group with the synthesis of oligo-1,2-naphthylenes. Using a strategic and iterative sequence of oxidation and building block addition followed by the stereoselective arene-forming aldol condensation developed earlier in our group,^[51] the synthesis of configurationally stable oligo-1,2-naphthylenes was achieved (Scheme 53, top).^[53] Based on the highly effective atropisomeric synthesis of rotationally restricted amides (Scheme 53, middle),^[52] we envisioned a study of more complex systems involving multiple stereogenic axes. We envisaged to investigate configurationally stable aromatic amides, bearing bulky substituents, ultimately leading to restricted rotations about the Ar-C(O), C(O)-N and Ar-N bonds (Scheme 53, bottom).

configurationally stable stereoisomers (Scheme 54).^[158–161]

Scheme 54: Possible stereoisomers (top) and reported rotational barriers of aromatic amides (bottom).

Based on the retrosynthetic strategy previously described to obtain mono-axis atropisomeric aromatic amides,^[52] a similar approach was designed (Scheme 55). Therefore, compound **84** could be obtained after a semi-hydrogenation/oxidation/aldol condensation sequence from compound **85**. Furthermore, compound **85** would originate from a triflation followed by a Sonogashira cross-coupling of **86**. Finally, the latter could be accessed from the opening of lactone **88** by 2-*t*-Bu-aniline (Scheme 55).

Scheme 55: Retrosynthetic strategy for the synthesis of secondary amide substrate.

The substrate synthesis of our first multiaxis system started then from the addition of the 2-*t*-Bu-aniline to synthon **88** at 50 °C.¹ This reaction proceeded with full conversion without the need of an additional base (Scheme 56). The crude mixture was then engaged in a triflation reaction that gave compound **89** after 30 min with an overall yield of 83% over two steps. After a Sonogashira cross-coupling with 3-butynol (44% yield), intermediate **85** was selectively semi-hydrogenated to its corresponding (*Z*)-alkene using H₂ and Pd/C. The subsequent oxidation with DMP led to the desired aldehyde which then reacted with KHCO₃ and the racemic tetrazole catalyst to the aldol condensation product. The final addition of NaBH₄ in EtOH did not successfully reduce the alcohol therefore we tried to isolate aldehyde **91** to test other reaction conditions. Despite the purification issues due to the low stability of the compound, we managed to explore the reduction of **91** by LiBH₄ in THF and DIBAL-H in toluene.^[162] The former reduction did not yield any product, whereas the latter led to decomposition.

¹ Synthon **88** was graciously supplied by Dr. Vincent C. Fäseke.

Reduction* conditions : $\text{NaBH}_4, \text{EtOH, RT}$ // $\text{LiBH}_4, \text{THF, RT}$ // $\text{DIBAL-H, toluene, } -78^\circ\text{C}$.

Scheme 56: Retrosynthetic strategy and synthesis of a primary amide substrate.

Considering the beforementioned issues with the reduction of **91**, we decided to move on to a more stable substrate by introducing a methyl group on the nitrogen. Applying the conditions of Sivaguru and coworkers, 2-*tert*-butylaniline and 2-phenylaniline were converted to their *N*-Methyl analogues in a two-step procedure.^[163] Related to an Escheiwer-Clarke methylation, the first step consists of condensation of the aniline and the succinimide with formaldehyde in EtOH (Scheme 57). The resulting adduct was then isolated as a white crystalline powder and reduced by NaBH_4 in DMSO to obtain the desired product in good yields (72% for **92a** and 84% for **92b**).

With our two newly synthesized starting materials in hand, we carried on with the substrate synthesis (Scheme 57). Lactone opening followed by the triflation proceeded smoothly for both 2-*tert*-butylaniline and 2-phenylaniline in good yields (74% for **93a** and 60% for **93b**). Interestingly, a 2D TLC revealed the presence of *cis* and *trans* stereoisomers confirmed by

NMR with a ratio of 1:2. The subsequent Sonogashira cross-coupling with 3-butynol successfully produced the alkyne intermediates **94a** and **94b** with 79% and 69% yield, with a *cis/trans* ratio of 1:5. However, the partial reduction to the (*Z*)-alkene **95** was only achieved with the *tert*-butyl amide intermediate **94a**.

Scheme 57: Methylation by reductive amination (top) and substrate synthesis of secondary amides (bottom).

Although several reaction conditions for the semi-hydrogenation of **94b** were explored, the selective reduction remained unsuccessful (Table 4).

Entry ^{a, b}	Catalyst	Solvent	Observations

5	Pd(CaCO ₃)	Pyridine	No conversion after 1 h
6	Pd(CaCO ₃)	MeOH/Pyridine	Over reduction after 2 h
7	Pd(CaCO ₃)	MeOH/Pyridine	Over reduction after 2 h
8	Lindlar + quinoline	EtOH	No conversion after 15 h

[a] Reaction performed with 100 μmol of **94b**; [b] Conversion determined by NMR.

Table 4: Reaction conditions for the semi-hydrogenation of substrate **94b**.

Nevertheless, the synthesis proceeded with *tert*-butyl amide **95a** going through an oxidation with DMP followed by an aldol condensation catalyzed by (*S*)-(-)-5-(2-Pyrrolidinyl)-1H-tetrazole. After the oxidation, an aliquot was reacted with the racemic version of the proline tetrazole catalyst to identify the enantiomers by HPLC. Finally, the reduction delivered compound **96** with 33% overall yield over four steps. Only one diastereomer could be isolated by column chromatography. However, the NMR of the crude mixture showed a *cis/trans* ratio of 1:3. After extensive analysis of the spectra by NMR,² we could identify the topology of the newly synthesized rotationally restricted amide **96** (Scheme 58).

² NMR measurement together with PD Dr. Daniel Häussinger.

aS (Ar-CO)–*trans* (N-CO)–*aR* (Ar-N)

Scheme 58: NOE correlation for the identification of compound **96**.

A strong NOE correlating the *t*-Bu group and the CH_2OH was observed as well as another correlation between C5H and C6'H , indicating that the major product isolated is the *aS* (Ar-C(O))–*trans* (N-C(O))–*aR* (Ar-N). An HPLC analysis was also conducted on the crude mixture providing further information into the configuration of this amide. Surprisingly, the results revealed the presence of four different enantiomers instead of the eight expected. The *cis/trans* ratio of 3:1 was confirmed by HPLC and interestingly, an e.r. of 87:13 was detected for the *trans* against an e.r. of 75:25 for the *cis*. This outcome implies that a substantial stereocontrol was achieved over one of the three axes which would most likely be the Ar-C(O) bond. However, considering the rotational barriers described in literature for a similar type of anilides (Scheme 54),^[23] the absence of the two other pairs of enantiomers was perceived as quite peculiar. Particularly as the rotation about the Ar-N bond is not restricted enough to be visible by NMR nor HPLC.

In order to further study the stability of compound **96**, the crude mixture was heated up in CDCl_3 at 46 °C for 72 h (Table 5 and 6). Over time, the population of the *trans*-isomer was enhanced at the expense of the *cis*-isomer to reach a *trans/cis* ratio of 93:8. These results were confirmed both by NMR spectroscopy and HPLC. According to Curran and co-workers,^[164] electronic factors overtake the steric hindrance in the case of *N*-methylanilides. The electrostatic repulsion between the π -electrons of the aniline moiety and the lone pairs of the oxygen would explain the observed conformation of the major product. Moreover, considering the aromatic nature of the phenanthrene moiety, a π - π stacking with the aniline system could also be another factor that stabilizes the conformational outcome of the reaction.

4	86	14	72	87	13

Table 6: NMR analysis of compound **6** in CDCl₃ at 46 °C.

Excited about these first results, we were curious to further examine the influence of the substituents in key positions over the topology of these anilides. Although we could not reach the derivative with a phenyl group instead of the *t*-Bu on the aniline moiety to explore the

effect of the *ortho*-substituents, a more dynamic system with a naphthalene core replacing the phenanthrene was envisaged. Without a *peri*-substituent, the rotational barrier about the Ar-C(O) bond would significantly decrease resulting in the Ar-N bond being the only element with possible stereocontrol. Enlightened by this hypothesis, we began the synthesis of the naphthalene derivative (Scheme 59).

Following the previous strategy, we first prepared the corresponding lactone **97** using a Friedel-Crafts reaction with oxalyl chloride and phenol. The crude mixture of **97** was then directly submitted to undergo a nucleophilic ring opening by the 2-*tert*-butyl-aniline followed by a triflation to give intermediate **98**. This first sequence was achieved smoothly with an overall yield of 53% (three steps). The Sonogashira cross-coupling with 3-butyne-1-ol using the conditions previously employed did not yield any product. However, by using a combination of triethylamine instead of diisopropylamine and adding an excess of TBAI, the corresponding alkyne derivative **99** was obtained in good yield (79%). Palladium on charcoal in pyridine did not yield any conversion to the corresponding alkene. While *in-situ* generated Borohydride-Nickel (Ni-P2) was used, which allowed the successful semi-hydrogenation to the (*E*)-isomer. Finally, the oxidation/aldol-condensation/reduction sequence delivered compound **101** in 12% overall yield (four steps), with a *cis/trans* ratio of 2:3. The low yield is attributed to the slow and partial oxidation of the alcohol with DMP.

Scheme 59: Substrate synthesis of the naphthalene system.

Following purification, the *cis* and *trans* compounds could not be separated however we were able to determine their molecular arrangement by NMR analysis (Scheme 60).³

Scheme 60: NOE correlation for the identification of compound **101**.

³ NMR measurement together with PD Dr. Daniel Häussinger.

A significant correlation between the CH_2OH group and $\text{C6}'\text{H}$ on one side and the methyl group on the other indicates clearly a *trans* configuration. This result is substantiated by a strong NOE between the *t*-Bu group and C5H . For the *cis* product, an intense correlation between C5H and the methyl group is observed. Moreover, a strong NOE is also detected between the CH_2OH group and *t*-Bu group.

Confirming our hypothesis of a more dynamic system, the HPLC analysis of the crude mixture of **101** conducted with the enantiopure catalyst displays an identical chromatogram to the racemic one, with a ratio of *cis/trans* 2:3 consistent with the NMR data. This result corroborates the importance of a substituent in *peri*-position of the naphthalene ring in order to increase the rotational barrier about the Ar-CO bond and induce selectivity. However, once again, only four stereoisomers were detected which would indicate a free rotation about the Ar-N bond.

In order to increase the rotational barrier of the Ar-N bond to obtain the missing pair of enantiomers and to observe the effect on the *cis/trans* ratio, we decided to replace the methyl group with an *i*-Pr group on the nitrogen. With the conditions described in a patent,^[165] the synthesis of compound **102** using $\text{NaBH}(\text{OAc})_3$ with acetone in acetic acid was achieved in good yields (89%). Despite the use of triethylamine and increased temperatures, the low nucleophilicity due the steric hindrance of aniline **102** led to traces amounts of the α -ketoamide product. However, the latter proved to be unreactive under triflation conditions (Scheme 61). Accordingly, the synthesis of this substrate was not pursued any further.

Scheme 61: Substrate synthesis attempt with N-isopropyl group.

In conclusion, we successfully achieved the synthesis and the study of a rotationally restricted multi-axis phenanthrene system with substantial selectivity (*cis/trans* ratio of 1:3 and

e.r. *trans* = 87:13 and e.r. *cis* = 75:25). An efficient synthetic sequence with fine-tuned conditions including a Sonogashira cross coupling and a selective semi-hydrogenation allowed us to prepare a more dynamic naphthalene system to pursue our investigations. Surprisingly, both systems indicated a restricted rotation about the Ar-C(O) and N-C(O) bonds however, the absence in both systems of a third pair of enantiomers suggested that the Ar-N bond is rotating freely. Further research involving the synthesis of an alternative route to obtain the isopropyl derivative, with an installation at a later stage using the route previously described for the secondary amide, could be explored.

2.1.3 Enantioselective arene forming aldol condensation towards the formation of paracyclophanes

Since their discovery by Lüttringhaus in 1941,^[58] cyclophanes have always been a fascination for scientists as a result of their peculiar “handle-shaped” structure. Originally called *ansa*-compound for this reason (*ansa* = handle in latin), their chirality arises from the positioning of the alkyl chain extending out of the aromatic ring plane. Thus, the rotational barrier of these compounds is mainly influenced by two factors: first, the length and rigidity of the handle on one side and second, the bulkiness of the substituents on the aryl ring on the other (Scheme 62, top).^[166] Considering our previous experience with rotationally restricted multi-axis systems, we decided to take a step further in exploring stereogenic planes. Relying on the enantioselective arene forming aldol condensation well-established in our group, we envisioned the synthesis of an enantiopure paracyclophane with a phenanthrene core and an alkyl chain of 15 methylene units (Scheme 62, bottom).

Scheme 62: Paracyclophanes and their rotational barrier (top) and synthesis of enantiopure paracyclophanes (bottom).

A synthetic strategy which relies on the initial formation of the cyclophane prior to the functionalization of the aromatic core was embraced (Scheme 63). Consequently, the β,γ -unsaturated aldehyde **105** could be obtained from the dibromo-naphthalene intermediate **106** via a mono-Sonogashira cross-coupling followed by a semi-hydrogenation. A subsequent functional group conversion of the bromine into the corresponding aldehyde would then take place. The naphthalene moiety can be installed *via* the formation of a benzyne on the tetrabromophenylcyclophane **107** which would undergo a Diels-Alder cycloaddition with furane followed by a deoxygenation. Finally, intermediate **107** could be achieved by full bromination of the phenylparacyclophane **108**, the synthesis of which is extensively described by Yamamoto and coworkers.^[167]

Scheme 63: Retrosynthetic strategy for the preparation of enantiopure paracyclophanes.

The synthesis started with the elimination of water from the tertiary propargylic alcohol **111** under acidic conditions, as reported by Tabacchi *et al.* (Scheme 64).^[168] An *in-situ* distillation from the reaction mixture allowed to obtain the desired 2-methyl-1-buten-3-yne **110**. The reaction of dilithiated **110** with commercially available 1,12-dibromododecane led to the efficient formation of bis-enyne **112** (95% yield). Subsequently, a palladium-catalyzed cyclisation using a hyper dilution method to avoid the formation of polymers allowed to obtain compound **113**. In order to remove the exomethylene group, ozonolysis followed by a double reduction with H₂ and Pd/C was performed. However, the low yield and long reaction time drove us to consider another method described by Arimoto and coworkers involving the use of Zn and TMSCl to fully reduce the double bond.^[169] This strategy led to our key intermediate **108** with good yield (66%).

Scheme 64: Substrate synthesis of paraphenylcyclophane.

With the phenyl paracyclophane **108** in hand, we proceeded to examine several reaction conditions for its fourfold bromination (Table 7). The conditions described by Hart and coworkers (Table 7, entry **1**) led to decomposition.^[170] When using catalytic amount of iodine (Table 7, entry **2**) at lower temperature as described by Watson *et al.*, only partial conversion was achieved with undesired bromination on the alkyl chain.^[171] Replacement of I₂ with sub-stoichiometric amounts of elemental Fe (Table 7, entry **3**) as reported by Caster and coworkers produced selective bromination of the phenyl ring. However, a mixture of compounds was obtained.^[172] Finally, a good conversion was achieved when using a mixture of iodine and iron (Table 7, entry **4**) with 44% yield. Despite our efforts to optimize the reaction conditions, the isolated yield did not exceed 50% by using sub-stoichiometric amounts of AlBr₃ however, the reaction time could be significantly decreased (Table 7, entry **9**).

Entry ^a	Br ₂ (number of eq.)	Catalyst	Solvent	Temperature	Observations

[a] Reaction performed with 100 μmol of **109**; [b] Isolated yield.

Table 7: Reaction conditions for full bromination.

Nevertheless, we pursued the synthesis of **106** with a Diels-Alder reaction between furane and the *in-situ* formed benzyne from precursor **107** (Scheme 65). The obtained bridged intermediate was immediately deoxygenated by TiCl₄ to afford compound **106** in 33% yield over two steps.^[173] Using *n*-BuLi and DMF, we were aiming to selectively transform one bromine to the corresponding aldehyde **115**. However, after purification, we could only isolate the dehalogenated compound **116**.

Scheme 65: Synthesis of naphthaldehyde derivative **116**.

To gather more information about the rotational behavior of **116**, several HPLC analysis were conducted. The results show two peaks with a small plateau at RT which indicates that the two enantiomers are interconverting during elution (see Experimental section).^[174] As expected, increasing the temperature (40 °C) rose the height of the plateau indicating a faster interconversion. On the contrary, at 0 °C, we observed distinctly two peaks of the two enantiomers with a 50:50 ratio.

In order to avoid dehalogenation, we decided to install the β,γ -unsaturated alcohol chain starting first with the Sonogashira cross-coupling with 3-butynol. Unfortunately, despite several attempts with various reaction conditions, the bromine position remained unreactive (Table 8). The outcome of the reaction was unchanged when using the tetrabromoparacyclophane **107** as the starting material under the same reaction conditions.

Entry ^{a, b}	Base	Catalyst	Solvent	Temperature	Observation

[a] Reaction performed with 100 μmol of **106** and **107**; [b] NMR analysis.

Table 8: Sonogashira cross-coupling reaction conditions.

To overcome the low reactivity of the brominated compounds **106** and **107**, a Finkelstein reaction^[175] was performed to turn the bromine into a more reactive iodine intermediate. However, once more, only starting material was observed (Scheme 66).

Scheme 66: Finkelstein attempt.

Focusing on the obtained aldehyde **116**, an aldol condensation reaction as well as various nucleophilic additions were investigated to study further the stereodynamic of these products (Table 9). Nonetheless, the aldehyde remained unreactive in all cases.

<p style="text-align: center;">116</p>		<p>Nu⁻ = PhMgBr, NaphtMgBr, PhLi,</p> <p style="text-align: center;">BB</p>

[a] Reaction performed with 100 μmol of **116**; [b] NMR analysis.

Table 9: Reaction conditions for nucleophilic addition to the aldehyde **116**.

Because of the lack of reactivity of the aldehyde, a step back in the synthesis was taken. Dibromo naphthaldehyde **106** was used after halogen metal exchange as a nucleophile with benzaldehyde (Table 10). However, despite various reaction conditions tested, no conversion to the desired product was obtained.

Entry ^{a, b}	Conditions	Observation
1	<i>n</i> -BuLi, Et ₂ O/THF, – 98 °C to RT	No conversion
2	<i>n</i> -BuLi, <i>i</i> -PrMgCl (0.2 eq), Et ₂ O, – 98 °C to RT	No conversion
3	Mg, Et ₂ O, 50 °C	No conversion

[a] Reaction performed with 100 μmol of **107**; [b] NMR analysis.

Table 10: Reaction conditions for the nucleophilic addition of **17** to benzaldehyde.

Following the previous strategy to form the naphthalene ring, a Diels-Alder reaction with the *in-situ* formed benzyne did not yield any product with Danishefsky's diene nor methyl 3-methyl-2-furoate (Scheme 67).

Scheme 67: Diels-Alder reaction with compound **106**.

In conclusion, we achieved the synthesis of paracyclophane **116** which presents interesting stereolabile properties. An efficient synthetic strategy relying on the initial formation of the handle followed by a functionalization coupled with optimized reaction conditions allowed the construction of several derivatives with a naphthalene core. The analysis of compound **116** revealed an interconversion of the two enantiomers at RT which already suggests a slight hindrance of the handle. This result implies that further catalytic reaction to selectively form one of the enantiomers would perform through a dynamic kinetic resolution mechanism.

2.2 SYNTHESIS OF ACRIDINIUM SALTS FOR PHOTOREDOX CATALYSIS

2.2.1 Large scale optimization of the first generation of acridinium salts⁴

2.2.1.1 *Synthesis of acridinium salts with unsubstituted core*⁵

Acridinium salts are important members of the organic photoredox catalyst toolbox and are known for their powerful oxidative properties in the singlet excited state.^[106,176] Pioneered by Fukuzumi, and further developed by Nicewicz, their synthesis remains somewhat rigid (see chapter **1.2.1**).^[116,177] Using a method involving the addition of 1,5-bifunctional organometallic reagents to carboxylic acid esters developed in our group, we undertook the synthesis of 9,10-substituted acridinium salts (Scheme 68).^[173,178]

⁴ Together with Christian Fischer.

⁵ Reactions performed by Lukas Schneider as part of his student's project.

Scheme 68: Synthetic strategies for the synthesis of acridinium salts: Fukuzumi (top), Nicewicz (middle), our approach (bottom).

Pursuing the strategy previously developed to obtain 3,6-disubstituted acridinium salts,^[120] we started our synthesis with a Buchwald-Hartwig cross-coupling between 2-bromoaniline **124** and 2-bromoiodobenzene **125** which gave the corresponding secondary aniline **126** in 74% yield (Scheme 69). After methylation with iodomethane and sodium hydride in THF, we received intermediate **127** in very good yield (81%). Upon addition of elemental magnesium, **127** was transformed into a 1,5-bifunctional Grignard reagent that reacted with different carboxylic acid esters. A final dehydration with HBr yielded compounds **128a** and **128b** in moderate to good yields (63% and 78%, respectively).

Scheme 69: Synthesis of 9,10-substituted acridinium salts.

Excited that our method could also apply to acridinium salts with an unsubstituted core, we initiated the study of the photophysical properties of **128a** and **128b**. As expected, both compounds showed strong oxidizing properties due to the lack of substituent on the acridine moiety. Interestingly, catalyst **128a** exhibited a higher excited state reduction potential (Table 11, $E_{1/2} [\text{P}^*/\text{P}^-] = +2.32\text{ V vs SCE}$) compared to the Fukuzumi catalyst ($E_{1/2} [\text{P}^*/\text{P}^-] = +2.18\text{ V vs SCE}$). On the other hand, **128b** displayed a similar excited state reduction potential ($E_{1/2} [\text{P}^*/\text{P}^-] = +2.21\text{ V vs SCE}$), indicating the influence of electron density at the phenyl moiety.

Dye	λ_{abs} [nm] ^a	λ_{em} [nm] ^a	$E_{0,0}$ [eV] ^a	$E_{1/2}(\text{P}/\text{P}^-)$ [V] ^b	$E_{1/2}(\text{P}^*/\text{P}^-)$ [V]

Table 11: Photophysical properties of compounds **128a** and **128b**.

2.2.1.2 Large scale synthesis of the first generation of acridinium salts

Due to their interesting redox properties and their many applications in photoredox catalysis, the scalable synthesis of acridinium salts represents a major challenge for the development of sustainable alternatives to precious metal complexes in industry. A recent approach published by Nicewicz *et al.* involving a late stage nucleophilic substitution of xanthylium dyes allowed them to achieve the synthesis of various acridinium salts in multi-gram scale (Scheme 70).^[117] Considering the remarkable performance of acridinium salt **129a** in dual Ni/photoredox catalysis, we tackled its large-scale synthesis. As shown by Benniston and coworkers,^[179] oxidation of the methyl group on the *para*-position of the mesityl moiety could influence the stability of the dye. For this reason, the multi-gram synthesis of the acridinium salt **129b** with *m*-xylyl moiety was also envisaged.

Scheme 70: Large-scale synthesis of acridinium salts conducted by Nicewicz (top), photostability studies reported by Benniston (middle), overview of the multi-gram synthesis of compounds **129a** and **129b** (bottom).

Starting with the conditions previously described, we initiated our investigations on 20 g (100 mmol) of compound **130** (Scheme 71). The nitration gave full conversion to the desired regioisomer and the pure compound was obtained after precipitation in water. The following reduction with $\text{SnCl}_2 \cdot \text{H}_2\text{O}$ led to the corresponding aniline **131** in 58% yield (over two steps).

Scheme 71: Initial conditions for the nitration and reduction of compound **130**.

Encouraged by these results, we moved on to a larger scale nitration (100 g, 500 mmol). Unfortunately, after several attempts, only a mixture of regioisomers was obtained with varying ratios. This is likely due to a partial protonation of the dimethyl amino group despite the use of a large excess of sulfuric acid. To overcome this issue, we decided to split the nitration into two steps (Scheme 72). To ensure full protonation, **130** was stirred with stoichiometric amount of aq. HNO_3 in a 1:1 mixture of MTBE and THF in order to precipitate the corresponding nitric salt in the first step. Afterwards, in the second step, the addition of sulfuric acid formed the nitronium ion for the aromatic electrophilic substitution that led to the desired product **132** in good yield (52%). Without any further purification, compound **132** was reduced to aniline **131** using Fe and NH_4Cl . This method avoids the handling of tin chloride and led to the desired compound through a more fluid work up, without a tedious purification step.

Scheme 72: Final conditions for the nitration and reduction of compound **130**.

In the following step of the large-scale synthesis of **129**, the iodination of compound **131** using a Sandmeyer reaction proved to be extremely challenging (Table 12). Unreproducible results with different ratios of the desired compound coupled with tremendous purification issues led us to consider alternative pathways to compound **133**.

Entry ^a	Scale	Work up	Purification	Observations
1	20 mmol (4.3 g)	-	-	No conversion
2	2 mmol (430 mg)	-	-	Conversion to a side product
3	58 mmol (12.5 g)	Na ₂ SO ₃ /CH ₂ Cl ₂	Column Chromatography	100 mg of pure isolated compound
4	58 mmol (12.5 g)	Et ₂ O/NH ₄ OH/CH ₂ Cl ₂	-	< 1 g of isolated compound
5	5 mmol (1.08 g)	Et ₂ O/NH ₄ OH/CH ₂ Cl ₂	-	1:4 P/SP
6	20 mmol (4.3 g)	-	-	Conversion to a side product
7	10 mmol (2.15 g) ^a	Filtration through Alox	-	607 mg of impure compound
8	10 mmol (2.15 g) ^a	Filtration through Alox	-	2 g of impure compound

[a] The starting material was the corresponding HCl salt of **131**.

Table 12: Sandmeyer reaction attempts for the formation of **133**.

An alternative route had been previously described, consisting in a reductive amination/Finkelstein reaction/Bromination sequence. This strategy allowed us to successfully obtain compound **133** (Scheme 73).^[120] The reductive amination using aq. HCHO and NaBH₄ fully converted compound **134** to its dimethyl derivative which was engaged without further purification in a Finkelstein reaction to deliver **135** with an excellent yield (97%). The selective bromination led to the desired intermediate **133** after a recrystallization in *n*-hexane/EtOAc 4:1.

Scheme 73: Reductive amination/Finkelstein/bromination sequence.

The Buchwald-Hartwig cross-coupling between intermediate **131** and **133** proceeded swiftly to yield the corresponding coupling product **136** (70%). However, despite our efforts to optimize the purification, a column chromatography was inevitable in this case.

With this intermediate in hand, several alternatives were examined for the methylation step (Table 13). Unfortunately, all of these options failed.

Entry ^{a, b}	Conditions	Observations
1	(CHO) _n (10 eq), NaBH ₃ CN (4 eq), Acetic acid, 15 h, RT	Decomposition
2	Trioxane, Et ₃ SiH, TFA, CH ₂ Cl ₂ , 24 h, RT	No conversion

[a] Reaction performed on 1 mmol scale; [b] Analysis with NMR.

Table 13: Conditions for methylation.

Turning back to the original conditions using CH₃I and NaH, we could achieve the synthesis of our key intermediate **137** in good yield (71%) to give a significant amount (35 g) after a recrystallization in *n*-hexane/EtOAc 4:1 (Scheme 75). The formation of the 1,5-bifunctional organomagnesium reagent was easily completed after 3 h and the direct ester to acridinium transformation finally delivered almost 4 g of compounds **129a** and **129b** in very good yields (82% and 84% respectively).

Scheme 75: Methylation and direct ester to acridinium transformation.

Having synthesized a new acridinium salt, we moved on to measure its photophysical properties (Table 14). As anticipated the photophysical profile of **129b** is extremely similar to **129a** with identical excited and ground state reduction potentials (Table 14, $E_{1/2} [P^*/P^-] = +1.25$ V vs SCE). For this reason, we believe that organocatalyst **129b** could offer comparable performances in photoredox reaction with a slightly improved photostability.

Dye	λ_{abs} [nm] ^a	λ_{em} [nm] ^a	$E_{0,0}$ [eV] ^a	$E_{1/2}(P/P^-)$ [V] ^b	$E_{1/2}(P^*/P^-)$ [V]
129a	503	530	2.40	-1.15	+1.25
129b	504	533	2.40	-1.15	+1.25

[a]Measured in MeCN (15 $\mu\text{mol L}^{-1}$); [b]Measured in 0.1 mol L⁻¹ n Bu₄N·PF₆ in dry, degassed MeCN against SCE.

Table 14: Photophysical properties of compounds **129a** and **129b**.

In summary, we successfully completed a sustainable large-scale synthesis of compound **129a** and **129b** with optimized reaction conditions and purification procedures (Scheme 76). All products were obtained in good to excellent yields, primarily using the crude mixture or a recrystallized intermediate directly. Finally, the photophysical properties of **129b** showed promising results for potential photoredox activities.

Scheme 76: Final large-scale synthesis of **129a** and **129b**.

2.2.1.3 In depth study of the photophysical and photochemical properties of a peculiar acridinium photocatalyst⁶

With an excited state reduction potential approaching those of transition metal systems ($E_{1/2} [\text{P}^*/\text{P}^-] = +1.25 \text{ V vs SCE}$), **129a** displayed a peculiar activity in the Ni-dual catalytic cross-coupling reaction (Scheme 77).^[120] When compared to a wide variety of commonly used photoredox organocatalysts such as eosin Y, only **129a** followed the decarboxylative mechanism **A**, all the others led to the C-O cross-coupling product.^[108,180–182] Therefore, these results drove us to further investigate the mechanism behind this divergent pathway

⁶ Performed by Dr. Christoph Kerzig in the group of Prof. Dr. Oliver Wenger, University of Basel.

Scheme 77: Divergent pathway for the Ni-dual catalytic cross-coupling reaction.

According to MacMillan's described mechanism,^[183,184] **129a** undergoes a single electron transfer (SET) to oxidize the deprotonated proline derivative which after decarboxylation leads to the radical intermediate (Scheme 78, pathway A). A second catalytic cycle involving Ni(0) starts with the oxidative addition of the aryl halide to give a Ni(II) species which reacts with the radical forming a Ni(III) intermediate. Finally, the reductive elimination delivers the product and a last SET from the photocatalyst reduces Ni(I) to Ni(0) to complete the cycle. Contrarily, the other photocatalysts operate through a triplet-triplet energy transfer (TTET) to excite the aryl Ni(II) carboxylate in order to favor the reductive elimination leading to the *O*-aryl ester (Scheme 78, pathway B). Noticeably, the photocatalysts with high oxidative excited state reduction potentials such as the Fukuzumi catalyst led to either low conversion with a mixture of compounds or no product at all.

Scheme 78: General mechanism of the Ni-dual catalytic cross-coupling.

To gain insight into this singular reactivity, our investigations started with comparative DFT calculations between **129a** and the Fukuzumi catalyst.^[109] The results show a clear contrast in the nature of the lowest energetic electronic transitions (Figure 1). While a distinct CT (charge transfer) is observed between the mesityl moiety of the HOMO and the acridine core of the

LUMO for the Fukuzumi catalyst, the dimethyl amino groups of **129a** introduce a change to a π - π^* character. For this reason, the less energetic state of **129a** allows Ni-dual catalysis and multicomponent reactions whereas the Fukuzumi catalyst, as a highly oxidizing and reactive agent is not well-suited for such transformations.

Figure 1: DFT calculations (B3LYP/6-31+G(d,p), IEFPCM solvation with MeCN) of **129a** and the Fukuzumi catalyst.

We next examined the quantum states of **129a** and eosin Y. The singlet excited state reduction potentials of both catalysts are very similar (+1.25 V for **129a** against +1.23 V for eosin Y) therefore, they could both theoretically oxidize the carboxylate derivative.^[108,120,184,185] Moreover, the calculated triplet energy of **129a** $E_T = 1.89$ eV is identical to the one of eosin Y, both higher than the triplet energy of the aryl Ni(II) carboxylate ($E_T = 1.85$ eV).^[108,120,184,185] For this reason, both catalysts would thermodynamically be able to favor the formation of the *O*-aryl ester.

To understand the difference in the kinetics of these quantum states, laser flash photolysis (LFP) studies were conducted (Figure 2).^[186] The transient absorption (TA) spectrum of **129a** (in Ar-saturated acetonitrile upon 532 nm excitation with green laser) shows a long-lived species ($\tau = 330$ μ s). In order to identify this long-lived intermediate, a study of the reactivity towards aromatic hydrocarbons and more particularly anthracene was performed. A diffusion-controlled quenching and the formation of the anthracene triplet with its characteristic spectrum (Figure 2, upper inset) was observed. This result indicates clearly that

a triplet-triplet energy transfer (TTET) occurred via a Dexter mechanism between the triplet state of **129a** (donor) and the anthracene (acceptor). Further analysis helped determine that the triplet quantum yield of **129a** was about 7% with an estimated triplet energy of about 1.91 eV. These experimental results corroborates the DFT-calculated approximation ($E_T = 1.89$ eV).

Figure 2: Nanosecond laser flash photolysis (LFP) investigations of the triplet state of **129a** (20 μ M in deoxygenated MeCN) using 532 nm laser pulses of ~ 10 ns duration (pulse energy, 16 mJ). Main plot, transient absorption spectrum 500 ns after the laser pulse and time-integrated over 200 ns. Lower inset, kinetic transient absorption trace-monitored at 615 nm. Upper inset, transient absorption spectrum in the presence of anthracene (0.4 mM) recorded with a time delay of 3 μ s.

Considering that the triplet quantum yield of eosin Y is about 80%,^[187] this quantum state is believed to be the photoactive species.^[108] However, with a quantum yield of only 7% and according to Nicewicz studies on redox properties of acridinium photocatalysts,^[188] **129a** is more likely to react *via* its more populated singlet excited state. However, in light of the long-lived triplet state ($\tau = 330$ μ s) and the high triplet energy ($E_T = 1.91$ eV) displayed by **129a**, we were curious to test its reactivity. A triplet sensitized *trans*-to-*cis* photoisomerization of stilbene assay was thus conducted (Scheme 79). The results showed that the triplet state of **129a** can still remain active yielding 71% of the *cis*-stilbene (for thermodynamic reasons, the

cis-stilbene triplet state cannot be generated with **129a** as a triplet energy donor). Therefore, in absence of a competitive reaction pathway, **129a** can operate photochemical transformation through its triplet excited state.

Scheme 79: Stilbene photoisomerization essay.

Pursuing our analysis, we then focused on the study of the singlet excited state reactivity of eosin Y and **129a** through fluorescence quenching experiments with Boc-proline derived Cs- and K-carboxylates as substrates (Figure 3). Surprisingly, a longer natural lifetime of singlet excited state was observed for eosin Y ($\tau = 5.29$ ns) compared to **129a** ($\tau = 2.23$ ns). However, according to the Stern-Volmer plot, the quenching by the Cs salt of Boc-Proline was 50 times slower in the case of eosin Y than **129a**. This observation substantiates that only the singlet excited state of **129a** is able to perform an efficient quenching. This difference of kinetic reactivities is due to Coulomb interactions that have a significant influence on the quenching rate constants and could explain the diverging pathways of the two photocatalysts.

Figure 3: Fluorescence quenching studies of **129a** and eosin Y in deoxygenated DMF upon 473 nm excitation. Main plot, response function of the TCSPC instrument (IRF) and unquenched lifetimes of both emitters. Inset, Stern–Volmer plots using either K^+ - or Cs^+ -salt of Boc-L proline as quencher.

2.2.1.4 Modular synthesis of acridinium photocatalysts

The field of photoredox catalysis have been dominated by polypyridyl transition metal systems, especially Ir and Ru based complexes, because of their powerful and flexible properties.^[103,104,189,190] The high tunability of their ligands offers a great modularity of their photophysical features. The development of complementary organic photocatalysts opened up the area towards more sustainable alternatives.^[106–108] Among them, acridinium salts pioneered by Fukuzumi and later refined by Nicewicz are well-established photocatalysts with powerful oxidative properties.^[109,110,116] However, their synthetic modularity is limited by their traditional assembly. This observation associated with the photochemical findings about compound **129a** (see chapter above) guided us to design a modular approach for the synthesis of a variety of acridinium salts with a wide range of photophysical properties. The crucial step of this synthesis lies in the combination of a directed *ortho*-metalation (doM) with a halogen-metal exchange delivering a 1,5-bifunctional organolithiated reagent.^[120,121] Finally, this key intermediate reacts with diverse carboxylic acid esters to deliver the desired asymmetric acridinium salts (Scheme 80).

Scheme 80: Modular synthesis of acridinium salts.

Encouraged by the efficiency of the substrate synthesis previously developed, a similar strategy was envisaged using anisole derivatives to introduce the methoxy group essential for the upcoming doM (Scheme 81).⁷ *m*-Anisidine **138** was thus coupled to *ortho*-bromoiodobenzene **125** to deliver, upon methylation, intermediate **139a** in almost quantitative yields and significant amount (4 g). The coupling of aniline with *m*-iodoanisole was scaled-up and gave 35 g of the key intermediate **141** in very good yield (91%). This secondary aniline intermediate was then engaged in coupling reactions with *ortho*-bromoiodobenzene on one side and compound **141** on the other side to deliver precursors **139b** and **139c** in significant amounts (7 g and 27 g). Compound **139d** was obtained in good yield (93%) after the coupling of **138** and **133** but was not scaled-up similar to its analogues (Scheme 81 in grey). Finally, an iodination reaction allowed us to obtain 62 g of compound **143** which after coupling with **141** yielded precursor **139e** in 45% yield.

⁷ Large-scale reactions performed together with Markus Jakobi and Romaric Corsi as part of his internship.

Scheme 81: Synthesis of the bi- and tri-arylamine precursors.

With our bi- and tri-arylamine precursors in hand, we pursued our synthesis with the mixed metalation using *n*-BuLi at 65°C. A rapid halogen-metal exchange followed by a slower directed *ortho*-metalation (doM) supported by the methoxy group delivered the 1,5-

bifunctional organolithiated reagents. The *in-situ* reaction with a variety of carboxylic acid esters finally provided a large scope of asymmetric acridinium salts, some of which on a gram-scale with an optimized purification avoiding column chromatography (Scheme 82). Noticeably, the reaction with methyl benzoate delivered the corresponding acridinium dyes **144g**, **144h**, **144j**, **144l** in very good to excellent yields (86% – 98%), probably due to the lack of steric bulk. This would explain the lower yields obtained with the double *ortho*-substituted methyl 2,4,6-trimethyl benzoate and methyl 2,6-dimethyl benzoate on a larger scale (29% – 57%), although the reported yields for 100 μ mol reaction were significantly higher (71%).^[191] Finally, 1-methyl naphthoate could be easily converted to racemic acridinium salts **144c**, **144d**, and **144k** in moderate to excellent yield (49% – 91%).

Scheme 82: Synthesis of asymmetric acridinium salts (compounds not scaled-up in grey).

Following the success of acridinium salts **144-l**, we then moved on to study the photophysical properties of these newly synthesized dyes (Table 15).⁸ After investigating the emission

⁸ Performed together with Dr. Christoph Kerzig in the group of Prof. Dr. Oliver Wenger.

lifetimes of compounds **144a–l**, we were pleased to observe an average τ of about 1 ns which makes them all suitable for photocatalysis. Moreover, a broad range of excited state redox potential was achieved from $E_{1/2}(P^*/P^-) = +1.19$ V (**144d**) or $+1.23$ V (**144i**) akin to $\text{Ir}[\text{dF}(\text{CF}_3)\text{-ppy}]_2(\text{dtbbpy})^+$ ($E_{1/2}(P^*/P^-) = +1.21$ V) to $E_{1/2}(P^*/P^-) = +1.81$ V (**144h**), including $E_{1/2}(P^*/P^-) = +1.40$ V (**144b**, **144c**, **144j**) analogous to $\text{Ru}(\text{bpz})_3$. Noticeably, the presence of a dimethyl amino or methoxy group on the acridine core significantly contributes to the decrease of the excited state redox potential by around 0.3 to 0.4 V and 0.1 to 0.2 V, respectively. Finally, organocatalysts **144a–l** mostly display $\pi\text{-}\pi^*$ electronic transitions sometimes combined with charge transfer (CT). Only **144k** showed a pure charge transfer (CT) similarly to the Fukuzumi catalyst.

Dye	$E_{0,0}^a$ [eV]	E_T^b [eV]	$E_{1/2}(P/P^-)$ [V] ^c	$E_{1/2}(P^*/P^-)$ [V]	τ^a [ns]	HOMO-LUMO transition ^b

[a] Measured in MeCN ($15\ \mu\text{molL}^{-1}$); [b] DFT calculation; [c] Measured in $0.1\ \mu\text{molL}^{-1}$ *n*-Bu₄NPF₆ in degassed, dry MeCN against SCE.

Table 15: Photophysical properties of compounds **144a–l**.

To complete our inquiry, photostability studies were performed on catalysts **129a** and **144a**, **144f**, **144g**, **144l** (see experimental part). Highly diluted and degassed solutions of these six acridinium dyes (~ 10 to $\sim 30\ \mu\text{M}$) were thus irradiated and the UV/Vis absorption spectra were monitored over 1 h. The results show a complete decomposition of **129a** and an ongoing photodegradation for **144l**. Whereas **144a**, **144f**, **144g** exhibit an identical spectrum to those

of freshly prepared solutions. Moreover, no color change of the solution is observed for compounds **144a**, **144f**, **144g** which prompts us to conclude that they are completely stable under these irradiation conditions. We next compared our results to the well-known photocatalyst complex $[\text{Ru}(\text{bpy})_3](\text{PF}_6)_2$ under the same irradiation conditions. The outcome indicates an even faster photodegradation than our least stable acridinium salt **129a**, with a full decomposition after only 30 min. We can therefore assume that the presence of a dimethyl amino group on the acridine core leads to a lower stability of the organocatalyst. An ^1H -NMR analysis of several degradation products showed a disappearance of the $-\text{NMe}_2$ signal and the formation of new entities that would indicate a demethylation process. This hypothesis is also supported by several LC-MS measurements revealing m/z signals of demethylated acridinium salts. Surprisingly, according to the ^1H -NMR spectrum, the mesityl moiety remained intact although the oxidation of the $p\text{-CH}_3$ group was described by Benniston and coworkers for the Fukuzumi catalyst.^[179]

Thus, the variety of photophysical and electrochemical properties of these newly synthesized dyes confirmed successfully the modularity of our design. Furthermore, their performance in several benchmark reactions such as fluorination and [3+3] cycloaddition was demonstrated (Scheme 83).^[191–194] Therefore, their efficiency combined to their inherent photostability proved their ability to complement polypyridyl transition metal complexes.

**Scheme 83:** Benchmark reactions: [3+2] cycloaddition (top) and decarboxylative fluorination (bottom).

2.2.2 Synthesis of a new generation of acridinium salts ⁹

Our previous success with the modular synthesis of asymmetric acridinium dyes and the proven performance of organophotocatalyst **129a** inspired us to design the next generation of acridinium salts. Given the results of the photostability assay and the fast decomposition of **129a** through a demethylation process, we envisaged the synthesis of more photostable organocatalysts. A study on organic light-emitting diodes (OLEDs) published by Adachi and coworkers showed a high photoluminescence potency as well as an efficient thermally activated delayed fluorescence (TADF) of a series of carbazolyl dicyanobenzene (CDCBs) derivatives with carbazolyl donor moieties and cyanobenzene acceptor groups.^[195] Interested by the electronic donating properties of the carbazole and the possibility of a unique electronic transition due to its distorted geometry from the plane, we envisioned to introduce carbazolyl units to replace the dimethyl amino groups.^[196] Moreover, the high selectivity of 4CzIPN for the C-C cross-coupling product in the Ni-dual catalytic reaction previously described (see **2.2.1**) coupled with good photostability (58% residual catalyst), as reported by Zhang and coworkers, strengthened our belief in designing a synthesis of acridinium salts with carbazolyl motifs (Scheme 84).^[183,196]

Scheme 84: Design of a new generation of acridinium photocatalyst.

A retrosynthetic strategy in three steps was envisaged to access the desired product **152** through a direct ester to acridinium formation from intermediated **153** (Scheme 85). The latter could be achieved *via* a double Buchwald-Hartwig C-N cross-coupling between aniline and building block **154**. Finally, a nucleophilic aromatic substitution of tri-halogenated compound **156** using carbazole as the nucleophile would lead to **154**.

Scheme 85: Retrosynthetic strategy for the synthesis of photostable acridinium salt **152**.

Starting with the nucleophilic aromatic substitution, the standard conditions described by Dai and coworkers allowed us to obtain compound **154** in 28% yield. Despite several optimization attempts (Table 16), the yield could not be further improved.

Entry ^{a, b}	Base	Solvent	Temperature	Time	Observation
1	CS ₂ CO ₃	DMF	150 °C	24 h	28% ^c
2	CS ₂ CO ₃	-	200 °C	48 h	No conversion
3	CS ₂ CO ₃	DMSO	180 °C	48 h	< 5% conversion
4	K ₂ CO ₃	DMF	150 °C	48 h	< 5% conversion
5	NaH	THF	75 °C	3 h	decomposition

[a] Reaction performed on 1 mmol scale; [b] Conversion determined by NMR; [c] Isolated yield.

Table 16: Reaction conditions for the nucleophilic substitution.

Nevertheless, with building block **154** in hand we moved on to test the double C-N cross-coupling with aniline (Table 17). Several reaction conditions were thus investigated starting from a standard palladium catalyzed Buchwald-Hartwig cross-coupling using dppf as a ligand (Table 17, entry 1). Receiving only the mono-addition product **153a**, we replaced dppf by RuPhos to facilitate the second addition. To our satisfaction, some conversion to the desired product **153** was obtained with a ratio of 0.8 : 1 regarding the mono-addition product **153a** (Table 17, entry 2). In order to explore further reactions to achieve a higher conversion and better yields, we turned to Ullman couplings catalyzed by Cu (Table 17, entry 3–8). However, in all cases, we only observed the formation of the mono-addition product **153a**.

Entry a, b, c	Catalyst	Ligand/ Additive	Base	Solvent	Temperature	Product
1	$\text{Pd}_2(\text{dba})_3$	dppf	<i>t</i> -BuONa	toluene	110 °C	153a (94%) ^d
2	$\text{Pd}_2(\text{dba})_3$	RuPhos	<i>t</i> -BuONa	toluene	110 °C	153a/153 (1:0.8)
3	CuCl	Phenanthroline	KOH	toluene	110 °C	153a
4	Cu (powder)	18-crown-6	K_2CO_3	dichlorobenzene	180 °C	153a
5	Cu and CuI	-	K_2CO_3	diphenylether	190 °C	153a
6	CuI	DMEDA	K_2CO_3	DMF	110 °C ^{e,f}	153a
7	CuI	DMEDA	K_2CO_3	DMF	150 °C ^{e,f}	153a < 5 %
8	CuI	DMEDA	K_2CO_3	DMF	190 °C ^f	conversion to 153

[a] Reaction performed on a 100 μmol scale; [b] Conversion determined by NMR; [c] Reaction time of 12 h unless stated otherwise; [d] Isolated yield; [e] μwave ; [f] Reaction time of 5 h.

Table 17: Reaction conditions for double C-N cross coupling.

Coming back to our most successful attempt using Buchwald Hartwig cross-coupling conditions, we decided to screen ligands starting with the mono-addition product **153a** (Scheme 86). **CataXCium® A** achieved a slightly better conversion than **RuPhos** with 56% while **CyJohnPhos** and **DavePhos** led to conversion of 23 and 37% respectively. Every other tested catalyst did not yield any conversion.

[a] Reaction performed on a 100 μmol scale; [b] Conversion determined by NMR.

Scheme 86: Ligand Screening.

Encouraged by those results, we chose inexpensive RuPhos in order to test other reaction parameters. PEPPSI and $[(\pi\text{-allyl})\text{PdCl}]_2$ were thus investigated as alternative palladium sources. However, PEPPSI did not yield any product and $[(\pi\text{-allyl})\text{PdCl}]_2$ gave a similar conversion to $\text{Pd}_2(\text{dba})_3$ (approximately 40%). Moreover, the use of pre-ligated RuPhos Pd G2 and G3 did not improve the conversion. Replacing $\text{Na}t\text{-BuO}$ by $\text{K}t\text{-BuO}$ also did not have any further effect. Nevertheless, by using the standard conditions with RuPhos, we could obtain our key intermediate **153** in 33 % yield (Scheme 87). The formation of the Grignard reagent next took place in a mixture of THF/Me-THF/toluene because of the very low solubility of substrate **153**. The exchange was complete after 3 h and our 1,5-bifunctional organomagnesium reagent could successfully react with the mesityl methyl ester into the desired product **152** (Scheme 87).

Scheme 87: Completed synthesis of the new generation of acridinium salts.

Naturally, we were curious to examine the photophysical properties of **152** and to compare them with the dimethyl amino derivative **129a** (Table 18). **152** showed a bathochromic shift compared to **129a** with absorption and emission wavelengths of 543 nm and 566 nm respectively, which would have interesting application with green light. This fact can also be observed by the naked eye with **152** being a deep purple powder and **129a** an intense orange solid. However, the Stokes shift are very similar with around 25 nm for each compound. Finally, the reduction potential on the ground and excited state are drastically different with

the newly synthesized acridinium salt **152** displaying a higher oxidative power ($E_{1/2}(P^+/P^-) = 1.79$ V).

Dye	λ_{abs} [nm] ^a	λ_{em} [nm] ^a	$E_{0,0}$ [eV] ^a	$E_{1/2}(P/P^-)$ [V] ^b	$E_{1/2}(P^+/P^-)$ [V]
129a	503	530	2.40	-1.15	+1.25
152	543	566	2.23	-0.44	+1.79

[a] Measured in MeCN ($15 \mu\text{molL}^{-1}$); [b] Measured in $0.1 \mu\text{molL}^{-1}$ *n*-Bu₄NPF₆ in degassed, dry MeCN against SCE.

Table 18: Photophysical properties of **152**.

Thrilled with these preliminary results, we proceeded next to improve further the synthesis in order to scale-up **152**. We were also interested in introducing other substituents that would favor photostability instead of the carbazoyl units, such as diphenylamine moieties for example. Therefore, we started to explore alternative synthetic routes with an intermediate that would offer the possibility of a late stage functionalization and a more flexible synthesis (Scheme 88). Maintaining the direct ester to acridinium transformation to obtain the desired product, the same key intermediates **153** and **153b** could be received after a double Buchwald-Hartwig C-N cross-coupling with double triflated compound **166**. The latter would be achieved through a demethylation/triflation sequence of triarylamine **167**. Another double Buchwald-Hartwig C-N cross-coupling between aniline and triflate **168** would lead to **167**. Finally, **168** could easily be synthesized by a selective bromination of 3-methoxyphenol **169** followed by a triflation.

Scheme 88: Retrosynthetic analysis for an alternative route to **152** and **152a**.

The first steps proceeded smoothly with a selective bromination achieved with 78% yield followed by a triflation with 91% yield. However, after several failed attempts at cross-coupling **168** with aniline, our strategy was adjusted (Table 19).

Entry ^{a, b}	Catalyst	Ligand	Base	Solvent	Observation
1	Pd ₂ (dba) ₃	XantPhos	K ₃ PO ₄	toluene	No conversion
2	Pd ₂ (dba) ₃	(rac)-BINAP	CS ₂ CO ₃	toluene	Hydrolysis of the triflate
3^c	Pd ₂ (dba) ₃	RuPhos	<i>t</i> -BuONa	toluene	Hydrolysis of the triflate

[a] Reaction performed on a 100 μmol scale at 100 °C unless stated otherwise; [b] Observation determined by NMR; [c] Reaction performed at 110 °C.

Table 19: Reaction conditions for the double C-N cross-coupling.

Inspired by the scale-up synthesis of Nicewicz and coworkers,^[117] we envisaged a retrosynthetic pathway relying on a late stage nucleophilic aromatic substitution of xanthilium dye **170/170a** by aniline (Scheme 89). The direct ester to xanthylum salt

transformation should lead us from intermediate **171/171a** to **170a/170**. As previously described, a demethylation/triflation/double C-O cross-coupling could achieve **171a/171** from diarylether **172**. Finally, the coupling of triflate **168** with phenol **173**, both issued from **169** would result in compound **172**.

Scheme 89: Retrosynthetic strategy using a xanthilium dye intermediate.

Unfortunately, the C-O cross-coupling product **172** could not be achieved using standard conditions with XPhos Pd G2 (Scheme 90).

Scheme 90: C-O cross-coupling for the synthesis of intermediate **172**.

This failure drove us to seek another approach using a *de novo* construction of the carbazoyl moiety coupled to a more divergent strategy (Scheme 91). Therefore, retro synthetically, intermediate **153** could be obtained through the C-N cross-coupling of **174** with **178** followed by iodobenzene. Compound **174** could be achieved through coupling of commercially available **175** with iodonium salt **176**. The latter is easily prepared by oxidation of 2-

iodobiphenyl **177**. A similar coupling between **176** and **179** could lead to **178**. Finally, **179** could be formed through an iodination/reduction sequence from 4-bromonitrobenzene **180**.

Scheme 91: Retrosynthetic pathway with the de novo construction of the carbazoyl moiety.

The oxidation of compound **177** by *m*-CPBA and TFA according to the conditions described by Wen, Huang and coworkers,^[197] effortlessly led to iodonium **176** with 85% yield (Table 20). The first attempt of copper-catalyzed coupling with **175** gave a promising result with an isolated yield of 20% under the standard conditions reported by Wen, Huang and coworkers.^[198] However, despite our optimization attempts, the yield could not be improved any further, forcing us to disregard this new route (Table 20).

Entry ^{a, b}	Ligand	Solvent	Temperature	Observation
1	Et(OH) ₂	<i>i</i> -PrOH	85 °C	20% ^c
2	Et(OH) ₂	Toluene	110 °C	conversion + degradation products

[a] Reaction performed on a 100 μmol scale; [b] Observation determined by NMR; [c] Isolated yield.

Table 20: Reaction conditions for the coupling of **175** and the cyclic diphenyliodonium salt **176**.

In reference to our original approach, we reasoned that the steric hindrance induced by the bromine in *ortho* position would most likely hamper the second coupling. This would explain the low conversion and low yield for intermediate **153**. Therefore, the replacement of a bromine by a chlorine, significantly smaller yet still suitable for C-N cross coupling, might increase the conversion and thus the yield for an analogous intermediate.

Our retrosynthetic strategy relied on key intermediate **181** with chlorine instead of bromine (Scheme 92). This compound could be generated from **182** after a double C-N cross-coupling with two carbazoles followed by another one with iodobenzene. A C-N cross coupling between **183** and **184** could deliver **182**. Finally, **183** could easily be prepared directly from **184** by a Sandmeyer reaction.

Scheme 92: Retrosynthetic strategy with chlorinated intermediates.

Commercially available **184** underwent a Sandmeyer reaction to give **183** in very good yield (88%). The following C-N cross-coupling of **183** with **181** catalyzed by $\text{Pd}_2(\text{dba})_3$ and dppf resulted effortlessly in compound **182** with an identical yield (Scheme 93).

Scheme 93: Synthesis of compound **182**.

We then started to investigate the C-N cross coupling between **182** and the two carbazole units (Table 21). First adopting the conditions described by Yamakawa and coworkers,^[197] the product was isolated with only 17% yield because of a significant side product formation (Table 21, entry 1) which was also observed when replacing the *t*-BuXPhos by cBRIDP (Table 21, entry 3). Switching to standard conditions with RuPhos in refluxing toluene proceeded

unfortunately with a low conversion (Table 21, entry 2). Additionally, our attempt to turn to an Ullmann coupling was unsuccessful (Table 21, entry 4). Finally, by using *t*-BuXPhos in refluxing toluene we achieved full conversion to the desired product and isolated intermediate **185** with 72% yield (Table 21, entry 5).

Entry ^{a, b}	Catalyst	Ligand	Base	Solvent	Temperature	Observation
1	Pd ₂ dba ₃	<i>t</i> -BuXPhos	Nat-BuO	Xylene	140 °C	17% ^c
2	Pd ₂ dba ₃	RuPhos	Nat-BuO	Toluene	110 °C	< 20% conversion

4	CuI	Phenanthroline	K ₂ CO ₃	DMF	150 °C	< 10% conversion
5	Pd ₂ dba ₃	<i>t</i> -BuXPhos	Nat-BuO	Toluene	110 °C	72% ^c

[a] Reaction performed on a 100 μmol scale; [b] Observation determined by NMR; [c] Isolated yield.

Table 21: Optimization of the C-N cross-coupling with carbazole.

Encouraged by this success, we undertook the next challenging coupling between **185** and iodobenzene (Table 22). Unfortunately, no conversion to the desired product was observed, despite several optimization attempts.

Entry	Catalyst	Ligand	Base	Solvent	Temperature	Observation
1	Pd ₂ dba ₃	RuPhos	Na ^t -BuO	Toluene	110 °C	No conversion
2	CuCl	Phenanthroline	KOH	Toluene	110 °C	No conversion

5	NiCl ₂ (PPh ₃) ₂	PPh ₃	EtMgBr	THF/Toluene	100 °C	No conversion
6	CuCl	-	K ₂ CO ₃	DMSO	200 °C	No conversion

[a] Reaction performed on a 100 μmol scale; [b] Observation determined by NMR; [c] Isolated yield.

Table 22: Reaction conditions for the cross-coupling of **185** with iodobenzene.

Other coupling strategies involving a double C-N cross-coupling between **183** and aniline to get to intermediate **186** or the direct C-N cross-coupling of **182** with iodobenzene were also experimented. However, none of these options led to the desired product and prevented further synthetic steps (Scheme 94).

Scheme 94: C-N cross coupling strategies to obtain the acridinium dye precursor.

Scheme 95: Direct ester to acridinium transformation attempts.

Facing a challenging synthesis of symmetric photostable acridinium salts, we decided to focus our attention on asymmetric dyes with a methoxy group on one side of the acridine core. We thus began our investigation by the coupling of our previously synthesized building blocks **154** and **141** (Scheme 96). Surprisingly, instead of the expected coupling-product **189**, we isolated

and fully characterized two carbazole derivatives **190a** and **190b** originating from a C-H activation in *ortho* and *para* of the methoxy group (see experimental section). In the literature, this reaction was exhaustively studied by Fagnou and coworkers for the synthesis of similar compounds and natural products.^[199] Unfortunately, our attempts to circumvent this activation pathway by lowering the temperature did not yield any product.

Scheme 96: Unsought C-H activation for the synthesis of carbazole derivatives.

Aware of the synthetic complexity to install the carbazole motif, we decided to switch to a diphenylamine unit. An entirely new substrate route was thus designed starting with the palladium catalyzed C-N cross-coupling of 3-bromoiodobenzene **191** with diphenylamine **192** (Scheme 97). After 15 minutes, the conversion was complete, and aniline was directly added to the reaction mixture. Subsequently, the desired compound **193** underwent a second coupling, without any further purification, to deliver quantitatively intermediate **194**. Even though the purification of this compound proved to be challenging, we pursued the synthesis with the coupling of 3-iodoanisole **195**. To our delight, our key substrate **196** could be synthesized however, the product could not be purified by column chromatography. Further

investigations are currently ongoing to find recrystallization methods in order to purify this compound.

Scheme 97: Substrate synthesis of photostable asymmetric acridinium salts.

Nevertheless, we decided to engage this substrate into the direct ester to acridinium transformation with several carboxylic acid esters (Scheme 98). Four new photostable acridinium salts could be synthesized. However, despite multiple column chromatographies and recrystallization attempts, the purification of these compounds remained challenging.

Scheme 98: Direct ester to photostable acridinium salts.

Nonetheless, we were excited to explore the photostability of these newly synthesized dyes. Thus, using similar conditions described in **2.2.1**, we irradiated degassed solutions (30 μM) of **197a-b** for 24 h with blue light. NMR and HPLC analysis of both samples were identical to freshly prepared solutions which indicates the high inherent photostability of those dyes. Moreover, the study of the photophysical properties (Table 23) showed surprisingly different excited state reduction potentials for such analogous structures ($E_{1/2}(\text{P}^*/\text{P}^-) = +1.37\text{ V}$ and $+1.57\text{ V}$ for **197a** and **197b**, respectively). Compounds **197c-d** are currently under ongoing investigations.

Dye	λ_{abs} [nm] ^a	λ_{em} [nm] ^a	$E_{0,0}$ [eV] ^a	$E_{1/2}(\text{P}/\text{P}^-)$ [V] ^b	$E_{1/2}(\text{P}^*/\text{P}^-)$ [V]
197a	502	726	2.13	−0.760	+1.37
197b	504	698	2.34	−0.769	+1.57

[a] Measured in MeCN (15 μmolL^{-1}); [b] Measured in 0.1 μmolL^{-1} $n\text{-Bu}_4\text{NPF}_6$ in degassed, dry MeCN against SCE.

Table 23: Photophysical properties of **197a-b**.

In conclusion, we achieved the synthesis of five new photostable acridinium catalysts with carbazole or diphenylamine units to replace the labile dimethyl amino group. The challenging issues regarding the routes established to reach symmetric dyes with carbazole units drove us to consider asymmetric analogues bearing a methoxy group on one side and a

diphenylamine on the other side of the acridinium core. Finally, the photophysical properties measured showed an interesting excited state reduction potential for compound **197b** with potential application in trifluoromethylation reactions.

2.2.3 Application in photoredox catalysis

2.2.3.1 Photoredox deuteration¹⁰

Isotopic labelling is a key part of several important aspects in drug discovery. By enabling a signaling unit on a molecule without altering its function, this method can play a crucial role in the quantification of drug metabolites in ADME (Absorption, Distribution, Metabolism, Excretion) studies or in ligand-binding essays.^[200,201] Among these isotopes, deuterium-labeled compounds are commonly used due their availability and low-cost.^[202,203] Previously synthesized in multi-step procedures, the development of C-H activation promoted their single step reaction through a hydrogen isotope exchange (HIE).^[204] Taking advantage of the photoinduction of α -amino radicals perfected in their group, MacMillan and coworkers designed a photoredox catalyzed deuteration and tritiation of pharmaceutically relevant scaffolds.^[200] Therefore, we decided to use this transformation as a benchmarking reaction for our photocatalysts, using clomipramine **198** as a substrate (Table 24).

An average isotopic incorporation of seven deuterium atoms per molecule with a distribution between aliphatic and benzylic positions (C5, C6, C1', C3', NMe2) has been reported by MacMillan and co-workers using 4CzIPN [2,4,5,6-tetra(9H-carbazol-9-yl)isophthalonitrile] as photocatalyst. We thus tested several acridinium photocatalysts, under identical reaction conditions. Gratifyingly, a high selectivity for the aliphatic positions (C1' = 20%, C3' = 64%, NMe2 = 39%), with an average of four deuterium atoms per molecule was observed when using **129a** with 1 mol% catalyst loading. A similar pattern was observed when employing **129b** with an even higher selectivity for the C3' position (70%) and an identical average incorporation of 4 deuterium atoms per molecule. As the site of the label is crucial in regard to the metabolic pathway of the substrate, these results are promising for further investigation on other drug-like molecules.

¹⁰ Together with Christian Fischer.

Photocat. ^a	Yield ^b (%)	Average ² H/molecule	² H Incorporation ^c (%)				
			C5	C6	C1'	C3'	NMe ₂

2.2.3.2 Stilbene isomerization

After successful tests on benchmark reactions involving a singlet electron transfer mechanism (decarboxylative fluorination, [3+2] cycloaddition, deuteration), we decided to test the efficiency of the TTET of our photocatalysts. Therefore, a stilbene isomerization using identical conditions described in 2.2.1 for acridinium salts **129a** was performed (Table 25). It appears that the highly oxidative photocatalysts displaying a CT electronic transition were not able to efficiently perform the *cis* isomerization (**Fukuzumi**, **144a**, **144h**). On the contrary, the ones with a low excited state reduction potential coupled with a π - π^* electronic transition gave excellent results (**144b**, **144d**, **144e**) the best being acridinium salt **144i** with 84% conversion to the *cis*-stilbene.

Dye	<i>cis</i> -stilbene	Dye	<i>cis</i> -stilbene	Dye	<i>cis</i> -stilbene

Table 25: Acridinium Stilbene isomerization.

3 CONCLUSION AND OUTLOOK

3.1 ROTATIONALLY RESTRICTED SYSTEMS

The stereochemistry of different types of rotationally restricted systems was explored during this thesis. From the synthesis of compounds with quaternary stereocenter to macrocycles with a stereogenic plane including scaffolds with multi-axis systems, a detailed investigation about spatial positioning and molecular arrangement was conducted.

An enantiospecific electrophilic addition involving rotationally restricted enamine intermediates was first investigated. The use of *ortho*-substituted anilines bearing EDG as organocatalysts allowed the formation of α -fluorinated and chlorinated compounds. Nevertheless, only a low selectivity was achieved (10% ee) in spite of several attempts to increase the rotational barrier of the enamine intermediate. Further investigations could involve the use of a poly-substituted ketone bearing large functional groups as a substrate to increase the steric bulk of the enamine intermediate and therefore improve the selectivity. Moreover, a Lewis acid could enhance the reactivity of the ketone to allow the addition of the hindered secondary anilines (Scheme 99).

Scheme 99: Proposal for further investigations.

Progressing towards more complex structures, we tackled next the synthesis and study of rotationally restricted multi-axis systems. The preparation of atropisomeric aromatic amides with three stereogenic axes was thus successfully achieved, with substantial selectivity for the phenanthrene scaffold (*cis/trans* ratio of 1:3 and e.r. *trans* = 87:13 and e.r. *cis* = 75:25). An in-depth study of the molecular spatial arrangement of this compound was then conducted

to determine the nature of the major isomer and led us to extend the scope. Fine-tuned reaction conditions allowed the synthesis of a more dynamic naphthalene system that substantiated the hypothesis of a free rotation about the Ar-N bond as opposed to a rotational hindrance about the Ar-CO and N-CO bonds. Further research involving the synthesis of a derivative with a bulkier substituent than the methyl group on the nitrogen (*i*-Pr with an alternative route or *t*-Bu) could be explored in order to lock the configuration about the Ar-N bond and generate a third pair of enantiomers.

Finally, we explored compounds displaying a stereogenic plane with the synthesis of paracyclophanes. The *de novo* construction of a functionalized naphthalene core combined to an alkyl chain with fifteen methylene units was therefore obtained and revealed interesting stereolabile properties. Although synthetic issues prevented the completion of the substrate synthesis and thus the enantioselective arene forming aldol condensation step, an alternative to the Sonogashira cross-coupling could be envisaged. A Seyferth-Gilbert homologation using Ohira-Bestmann reagent followed by a lithiation and ring opening of an oxirane, would represent an interesting option for the synthesis of the corresponding alkyne (Scheme 100).

Scheme 100: Potential Seyferth-Gilbert reaction to complete the substrate synthesis.

3.2 SYNTHESIS OF ACRIDINIUM SALTS AND APPLICATION IN ORGANOPHOTOCATALYSIS

Efficient synthetic strategies to access a variety of acridinium salts with suitable photophysical properties were described. The direct transformation of esters into acridinium catalysts using 1,5-bifunctional organomagnesium reagents allowed the synthesis of photocatalysts with unsubstituted cores displaying high oxidative properties. A fine-tuning of reaction conditions and purification protocols allowed the large-scale synthesis of amino functionalized photocatalysts with attenuated photoredox features.

An extensive study of a divergent organophotocatalytic reaction pathway disclosed interesting photophysical and photochemical properties of amino acridinium catalysts. These findings guided a modular synthesis of organophotocatalysts with an extended range of excited state reduction potential, complementing the polypyridyl transition metal complexes. Using a combination of halogen-metal exchange with directed *ortho*-metalation, twelve new acridinium salts with various energetic electronic transitions and flexible triplet energies were obtained, some of them in gram-scale.

In order to improve the photostability, the design of a new generation of catalysts was then examined. Replacing the labile dimethyl amino group, five new photostable acridinium catalysts with carbazole or diphenylamine units combined with methoxy groups were prepared. An early analysis of the photophysical properties showed an interesting excited state reduction potential with potential application in trifluoromethylation reactions.

Finally, the utility of the catalysts was demonstrated by the deuteration of clomipramine, providing high selectivity for aliphatic positions and reaching an average of 4 deuterium atoms per molecule using low catalyst loadings. A stilbene isomerization study allowed to test the efficiency of the triplet excited state of the acridinium photocatalysts with up to 84% conversion to the *cis*-stilbene.

Some of these catalysts are part of a patent licensed by Solvias and will be soon commercially available.

4 EXPERIMENTAL SECTION

4.1 GENERAL INFORMATION

All reactions were carried out in dried glassware under an Ar atmosphere. All chemicals were reagent grade and used as supplied unless stated otherwise. (S)-2-fluoro-3-phenylpropan-1-ol (**2**),^[154] (S)-2-fluoro-3-phenylpropyl acetate (**3**),^[154] N-benzyl-4-chloro-2,5-dimethoxyaniline (**61**),^[205] N-benzyl-2-(*tert*-butyl)aniline (**62**),^[205] N-benzyl-[1,1'-biphenyl]-2-amine (**63**),^[205] N-benzyl-2-ethoxyaniline (**64**),^[205] N-benzyl-2-isopropylaniline (**65**),^[205] N-benzyl-2-methylaniline (**66**),^[205] N-benzyl-2-methoxyaniline (**67**),^[205] N-benzyl-2-chloroaniline (**68**),^[205] N-benzyl-2-(piperidin-1-yl)aniline (**69**),^[205] *tert*-butyl (S)-(2-hydroxy-1-phenylethyl)carbamate (**81a**),^[206] *tert*-butyl (S)-(1-hydroxy-3-phenylpropan-2-yl)carbamate (**81b**),^[206] 2-(*tert*-butyl)-N-methylaniline (**92a**),^[163] N-methyl-[1,1'-biphenyl]-2-amine (**92b**),^[163] 2-(*tert*-butyl)-N-isopropylaniline (**102**),^[207] 2-methylbut-1-en-3-yne (**110**),^[167] 3,16-dimethylenooctadeca-1,17-diyne (**112**),^[167] 2-methylene-1(1,4)-benzenacyclohexadecaphane (**113**),^[167] 1(1,4)-benzenacyclohexadecaphan-2-one (**114**),^[167] 1(1,4)-benzenacyclohexadecaphane (**108**),^[167,169] bis(2-bromophenyl)amine (**126**),^[208] 2-bromo-5-methoxyphenyl trifluoromethanesulfonate (**168**),^[209,210] 2-bromo-5-methoxyphenol (**173**),^[209] dibenzo[*b,d*]iodol-5-ium trifluoromethanesulfonate (**176**)^[198] were prepared according to a literature known procedure. Ozone was generated with an ozone generator *BMT 802 N* from *BMT Messtechnik GmbH* and oxygen from *Pangas* (quality = 5.0). *n*-BuLi solution in hexane was purchased from *Acros Organics* (Nr. 181271) and the concentration was determined by titration with 1,10-phenanthroline in THF against *s*-BuOH according to Eastham and Watson.^[211] Magnesium chips, 4-30 mesh, were purchased from Aldrich (Nr. 254118) and were cut freshly followed by heating with a heat gun under vacuum (10–2 mbar) directly in the reaction flask prior to use. All photoreactions were performed in a sealed Biotage® 2-5 mL microwave vial equipped with a 10 mm x 5 mm magnetic stir bar stirring at 1400 rpm. The vial was placed on a stirring plate laterally in 3 cm distance to a *Kessil LED A160WE Tuna Blue*, 40 W, adjusted to maximum intensity and white (I_{max} : 464 nm). A sideward fan was used to keep ambient temperature (~30 °C). All starting materials and reaction solvents were purchased from commercial sources and used without further purification. Solvents for extractions and column chromatography were technical grade and

distilled prior to use. Analytical thin layer column chromatography (TLC) was performed on pre-coated *Merck* silica gel 60 F254 plates (0.25 mm) and visualized by UV and VIS. Flash column chromatography was carried out on *Silicycle SiliaFlash* P60 (230–400 mesh). Concentration in vacuo was performed by rotary evaporation to ~ 10 mbar at 40 °C and drying at high vacuum at 10⁻² mbar and RT. ¹H NMR, ¹³C NMR and ¹⁹F spectra were recorded on a *Bruker Avance* III 500 MHz and *Avance* III 400 MHz spectrometer at 298 K in CDCl₃, CD₃OD or C₆D₆ supplied by Cambridge Isotope Laboratories. Chemical shifts (δ) are reported in ppm relative to tetramethylsilane (0.00 ppm). The multiplicities are reported in Hz as: s = singlet, br = broad singlet, d = doublet, t = triplet, q = quartet and m = multiplet. Melting points were measured on a *Büchi* M-565 melting point apparatus and are uncorrected. IR spectra were measured on a ATR *Varian Scimitar* 800 FT-IR spectrometer and reported in cm⁻¹. The intensities of the bands are reported as: w = weak, m = medium, s = strong. High-resolution mass spectrometry (HR-ESI) was performed by Dr. Michael Pfeffer of the University of Basel on a *Bruker maXis* 4G QTOF ESI mass spectrometer. X-ray crystallographic analysis was performed by Dr. Alessandro Prescimone of the University of Basel. Cyclic Voltammetry was performed in dry, degassed 0.1 molL⁻¹ tetra *n*-butylammonium hexafluorophosphate in MeCN. Voltammograms were recorded with a *Versastat3-200* potentiostat from Princeton Applied Research employing a glassy carbon disk working electrode, SCE reference electrode and a silver wire counter electrode and a potential sweep rate of 0.1 Vs⁻¹. The glassy carbon electrode and Ag wire were polished prior to measurement. UV/Vis spectroscopy was performed on a *Shimadzu* UV-1650 PC spectrometer and steady-state luminescence spectroscopy was performed on a *Fluorolog-3-22* instrument from Horiba Jobin-Yvon. Excitation occurred at the long-wavelength absorption band of the respective dye. All emission spectra were recorded in argon-saturated acetonitrile, and strongly diluted dye solutions (c < 15 μmol L⁻¹) were used to avoid inner filter effects. All spectra so obtained were corrected for the wavelength-dependent sensitivity of the spectrometer. Additional emission spectra of the pure solvent at all excitation and detection conditions were measured to ensure the absence of stray light or impurity signals. Fluorescent lifetime (τ) of a ~15 μmolL⁻¹ solution was measured using a *Hamamatsu Compact Fluorescence Lifetime Spectrometer C11367 QuantaTaurus- Tau* using an LED light source with excitation wavelength of 470 nm with a peak count of up to 10000 and repetition rate of 5 MHz. The fluorescence

decay was satisfactorily fit to a first order rate equation. All Data was handled with *Igor Pro* (Wavemetrics, Lake Oswego, OR, USA) and *Origin* (OriginLab, Northampton, MA).

4.2 EXPERIMENTAL PROCEDURES

4.2.1 Rotationally restricted systems

Enantiospecific electrophilic substitution through atropisomeric enamines

Methyl (*R*)-2-chloro-2-fluoro-3-phenylpropanoate (25**)**

To a solution of (2*S*)-fluoro-3-phenyl-propan-1-ol (38.5 mg, 0.25 mmol) in CH₃CN (2 mL) was added IBX (105 mg, 0.38 mmol) and the reaction mixture was stirred at reflux for 2 h. The IBX was filtered off and the solvent evaporated in vacuo. The residue was dissolved in CDCl₃ (2 mL) and cooled down to 0 °C before adding the aniline (10 mol%) and NCS (43.4 mg, 0.33 mmol). The reaction was allowed to warm up to RT and stirred for 24 h. The solution was diluted in THF/*t*-BuOH (1:1, 15 mL) and 2-methyl-2-butene was added. In another flask, NaClO₂ (45.2 mg, 0.50 mmol) and NaH₄PO₅ (138 mg, 1.00 mmol) were dissolved in water (3 mL) before the solution previously prepared was added over 2 min. The biphasic reaction mixture was stirred vigorously for 2 h at RT. HCl 1M solution (20 mL) was added and the aqueous layer was extracted with Et₂O (3 x 20 mL). The combined organic layer was extracted with NaOH 1M solution (5 x 12 mL) then acidified with conc. HCl. The aqueous layer was extracted with CH₂Cl₂ (5 x 12 mL), dried over Na₂SO₄ and the solvent was removed in vacuo. The residue was dissolved in MeOH (1 mL) and thionyl chloride (0.02 mL, 0.25 mmol) was added at 0 °C. The reaction mixture was stirred for 12 h at RT. The solvent was removed in vacuo and the crude was purified by column chromatography (Toluene 100%) to afford **25** as a colorless oil; yield: 0.8 mg (1.5% over three steps). This compound could not be scaled up to measure additional analytical data.

¹H NMR (400 MHz, CDCl₃): δ = 7.24 (m, 3H, CH_{ar}), 7.19 (m, 2H, CH_{ar}), 3.75 [s, 3 H, (CH₃)], 3.57 (d, 1H, CH_{aliphatic}), 3.51 (d, 1H, CH_{aliphatic}) .

¹⁹F NMR (471 MHz, CDCl₃): δ = - 116,79 (s, 1F, CF).

***N*-Benzyl-2-(diphenyl((trimethylsilyl)oxy)methyl)aniline (**79**)**

Prepared according to a modified literature procedure.^[212]

To a solution of methyl-anthranilate (806 mg, 5.33 mmol) and zinc chloride (872 mg, 6.4 mmol) in MeOH (17 mL) under argon was added benzaldehyde (0.65 mL, 6.4 mmol). The reaction mixture was cooled down to 0 °C and sodium cyanoborohydride (402 mg, 6.4 mmol) was added. The reaction mixture was stirred at reflux for 2 h. A solution of NaOH 1M (17 mL) was added and the aqueous layer was extracted with Et₂O (3 x 50 mL). The combined organic layer was washed with brine (50 mL), dried over Na₂SO₄ and the solvent was removed in vacuo. The crude was used without further purification in the next step.

Prepared according to a modified literature procedure.^[213]

Under argon, methyl 2-(benzylamino)benzoate (531 mg, 2.20 mmol) was dissolved in dry THF (5 mL) and cooled to 0 °C. PhMgBr (8.00 mL, 8.00 mmol) was added dropwise over 30 min. The reaction mixture was stirred overnight at RT. A sat. aqueous solution of NH₄Cl (5 mL) was added and the aqueous layer was extracted with CH₂Cl₂ (3 x 15 mL). The combined organic layer was washed with brine (10 mL), dried over Na₂SO₄ and the solvent was removed in vacuo. The residue was dissolved in CH₂Cl₂ (3 mL) at 0 °C and NEt₃ (0.40 mL, 2.86 mmol) as long as TMSOTf (0.52 mL, 2.86 mmol) were added dropwise. The reaction mixture was stirred 1 h at 0 °C the allowed to warm up to RT and stirred overnight. A sat. aqueous solution of NH₄Cl (10 mL) was added and the aqueous layer was extracted with CH₂Cl₂ (3 x 20 mL). The combined organic layer was washed with brine (15 mL), dried over Na₂SO₄ and the solvent was removed in vacuo. The crude mixture was purified by column chromatography (Pentane/CH₂Cl₂ 5:1) to afford **79** as a white solid; yield: 193 mg (22%); m.p. 67.0–83.3 °C; *R*_f = 0.27 (pentane/CH₂Cl₂ 1:1).

IR (ATR, neat): 3444m, 3022w, 2954w, 2364w, 1600m, 1514m, 1450m, 1323m, 1250s, 1160m, 1051s, 876m, 837s, 746s, 710s, 633m cm⁻¹.

¹H NMR (500 MHz, CDCl₃): δ = 7.49–7.40 (m, 10 H, CH_{ar}), 7.34–7.33 (m, 3 H, CH_{ar}), 7.27 (td, ³J = 7.8 Hz, ⁴J = 1.5 Hz 1 H, C5H), 7.10 (dd, ³J = 8.2 Hz, ⁴J = 1.6 Hz 1 H 1 H, C3H), 6.70–6.67 (m, 2

H, C₄H, C₆H), 5.61 (t, ³J = 5.60 Hz, 1 H, NH), 4.29 (d, ³J = 5.60 Hz, 2 H, CH₂), 0.00 [s, 9 H, 3 x (CH₃)].

¹³C NMR (125 MHz, CDCl₃): δ = 145.5 (C1), 144.0 (C_{ar}N), 137.61 (C_{ar}), 128.5 (C3), 127.1 (C2), 127.0 (C5), 126.4 (C_{ar}), 125.8 (C_{ar}), 125.5 (C_{ar}), 125.2 (C_{ar}), 125.0 (C_{ar}), 112.8 (C4), 109.5 (C6), 84.9 (CO), 45.8 (CH₂), 0.0 (CH₃).

2-(2-((2-(*Tert*-butyl)phenyl)(methyl)amino)-2-oxoacetyl)phenyl trifluoromethanesulfonate (98**)**

To a mixture of coumarandione (1.48 g, 10.0 mmol) in toluene (50 mL) was added 2-*t*-Bu-*N*-methylaniline **87** (1.96 mL, 12.0 mmol) and the reaction mixture was stirred for 16 h at 50 °C. The solvent was removed in vacuo and the residue was dissolved in CH₂Cl₂ (25 mL). Et₃N (1.50 mL, 10.7 mmol) and Tf₂O (2.69 mL, 16.0 mmol) were added at 0 °C. The reaction mixture was stirred for 1 h at RT and sat. aqueous solution of NH₄Cl (20 mL) was added. The aqueous layer was extracted with CH₂Cl₂ (3 x 50 mL), the combined organic layer was washed with brine (50 mL), dried over Na₂SO₄ and the solvent was removed in vacuo. The crude was purified by column chromatography (pentane/CH₂Cl₂ 1:1) to afford **98** as a yellow solid; yield: 2.33 g (53%); m.p. 106.8–108.3 °C; *R*_f = 0.32 and 0.47 (pentane/CH₂Cl₂ 3:2) for the *cis* and *trans* diastereoisomer, respectively.

IR (ATR, neat): 3734w, 2964w, 2361s, 1893m, 1651s, 1604m, 1489m, 1425s, 1212w, 1139m, 1049m, 893s, 776s, 651m cm⁻¹.

¹H NMR (500 MHz, CDCl₃): δ = 8.08–6.79 (m, *CH*_{ar}, *cis/trans* 1:2), 3.38–3.35 (s, *NCH*₃, *cis/trans* 1:2), 1.46–1.44 [s, 3 x (*CH*₃), *cis/trans* 1:2].

***N*-(2-(*Tert*-butyl)phenyl)-2-(2-(4-hydroxybut-1-yn-1-yl)phenyl)-*N*-methyl-2-oxoacetamide (99)**

To a solution of **98** (2.22 g, 5.00 mmol) in THF (25 mL) was added NEt_3 (5.00 mL, 35.6 mmol), $\text{Pd}(\text{PPh}_3)_2\text{Cl}_2$ (351 mg, 0.5 mmol), CuI (286 mg, 27.7 μmol), TBAI (3.69 g, 10.0 mmol) and finally 3-butyne-1-ol (1.14 mL, 15 mmol). The reaction mixture was heated for 5 h at 80 °C then the solvent was removed in vacuo. The residue dissolved in EtOAc (25 mL) was filtered through Celite and washed with more EtOAc (200 mL). The solvent was then removed in vacuo. The residue was purified by flash column chromatography (CH_2Cl_2 100% to $\text{CH}_2\text{Cl}_2/\text{EtOAc}$ 9:1) to obtain **99** as a light orange solid; yield: 910 mg (79%); m.p. 71.5–74.9 °C; R_f = 0.46 and 0.56 ($\text{CH}_2\text{Cl}_2/\text{EtOAc}$ 9:1) for the *cis* and *trans* diastereoisomer, respectively.

IR (ATR, neat): 3733w, 3629w, 3442w, 3361w, 2361s, 1733w, 1649m, 1559s, 1488w, 1390w, 1267w, 1153w, 1115w, 1051w, 957w, 917w, 847w, 757m, 645m cm^{-1} .

^1H NMR (500 MHz, CDCl_3): δ = 7.97–6.83 (m, CH_{ar} , *cis/trans* 1:5), 3.85–3.78 (m, $\text{C4}'''\text{H}$, *cis/trans* 1:5), 3.37–3.26 (s, NCH_3 , *cis/trans* 1:5), 2.74–2.66 (m, $\text{C3}'''\text{H}$, *cis/trans* 1:5), 1.45–1.42 [s, 3 x (CH_3), *cis/trans* 1:5].

HRMS (ESI): m/z [$\text{M} + \text{Na}^+$] calcd. for $\text{C}_{23}\text{H}_{25}\text{NNaO}_3^+$: 386.1727; found: 386.1725.

***N*-(2-(*Tert*-butyl)phenyl)-2-(hydroxymethyl)-*N*-methyl-1-naphthamide (101)**

To a solution of **99** (109 mg, 0.30 mmol) in EtOH (1 mL) was added ethylenediamine (1.05 mmol, 0.07 mL). In a separate flask Ni(OAc)₂•4H₂O (74.7 mg, 0.30 mmol) was dissolved in EtOH (0.5 mL) and was treated with a solution of NaBH₄ (11.3 mg, 0.30 mmol) in EtOH (0.3 mL) over 5 min at RT. The solution was stirred for 1 h at RT under an atmosphere of H₂. The resulting mixture was combined with the previously prepared solution of the alkyne and the reaction mixture was vigorously stirred at RT under an atmosphere of H₂ for 20 h. A sat. aqueous solution of NH₄Cl (2 mL) was added and the aqueous layer was extracted with Et₂O (3 x 5 mL). The combined organic layer was dried over Na₂SO₄ and evaporated in vacuo. The residue was dissolved in Et₂O (5 mL) and filtered through a plug of Celite to remove the resin. The solvent was removed in vacuo. The residue was dissolved in CDCl₃ (3 mL) and DMP was added (192 mg, 0.45 mmol). The reaction mixture was placed into an ultrasonic bath for 1 min then stirred at RT for 72 h. CDCl₃ (3 mL) was added along with KHCO₃ (453 mg, 4.52 mmol) and (*S*)-5-(2-Pyrrolidinyl)-1H-tetrazole (2.09 mg, 15 mol%). The flask was placed into an ultrasonic bath for 1 min and the reaction was stirred at RT for 5 h. EtOH (6 mL) and NaBH₄ (113 mg, 3.00 mmol) were added at RT and the mixture was stirred for 1 h. Sat aqueous solution of Rochelle salt (6 mL) was added. The organic layer was washed with brine (10 mL), dried over Na₂SO₄ and the solvent was removed in vacuo. The residue was purified by flash column chromatography (CH₂Cl₂ 100% to CH₂Cl₂/EtOAc 4:1) to obtain **101** as a transparent oil; yield: 12.0 mg (12%); *R*_f = 0.27 and 0.42 (CH₂Cl₂/EtOAc 4:1) for respectively the *cis* and *trans* diastereoisomer.

Paracyclophanes

1²,1³,1⁵,1⁶-Tetrabromo-1(1,4)-benzenacyclohexadecaphane (107)

Under argon, **108** (115 mg, 0.40 mmol) along with $AlBr_3$ (42.7 mg, 0.16 mmol) were introduced in a microwave tube at 0 °C. Bromine (0.21 mL, 4.00 mmol) was added and the reaction mixture was stirred overnight. The reaction mixture was diluted in CH_2Cl_2 (2 mL) and treated with a solution of KOH 20% (2 mL). The solvent was removed in vacuo and the residue was purified by recrystallization in EtOH (0.5 mL) to obtain **107** as a white solid; yield: 54 mg (22%); m.p. 100.0–112.8 °C; R_f = 0.7 (Pentane 100%).

IR (ATR, neat): 2923s, 2852s, 2361s, 1670w, 1543w, 1457m, 1342m, 1281w, 1092s, 977w, 962w, 819m, 726m, 660m cm^{-1} .

1H NMR (500 MHz, $CDCl_3$): δ = 3.40 (t, 3J = 6 Hz, 4 H, $C1'H_2$, $C15'H_2$), 1.70 (m, 4 H, $C14'H_2$, $C2'H_2$), 1.30–1.10 (m, 22 H, 11x CH_2).

^{13}C NMR (125 MHz, $CDCl_3$): δ = 143.2 ($C1$, $C4$), 128.2 ($C2$, $C3$, $C5$, $C6$), 40.8 ($C1'$, $C15'$), 29.0 (C_{al}), 28.4 (C_{al}), 28.3 ($C14'$, $C2'$), 28.2 (C_{al}), 27.7 (C_{al}), 27.1 (C_{al}).

1²,1³-Dibromo-1(1,4)-naphthalenacyclohexadecaphane (106)

Under argon, to a solution of **107** (903 mg, 1.50 mmol) and furane (0.76 mL, 10.5 mmol) in dry toluene (15 mL) was added a solution of *n*-BuLi (1.47 M, 1.12 mL, 1.65 mmol) at –23 °C. The reaction mixture was allowed to warm up to RT and was stirred overnight. The reaction

mixture was quenched with slow addition of methanol (0.2 mL) and washed with water. The aqueous layer was extracted with Et₂O (3 x 20 mL), the combined organic layer was dried over Na₂SO₄ and the solvent was removed in vacuo. The crude was used without further purification.

Under argon, TiCl₄ (1.12 mL, 10.2 mmol) was carefully added to a suspension of Zn dust (1.04 g, 15.9 mmol) in THF (26 mL) at 0 °C. The reaction mixture was stirred at reflux for 10 min. After cooling back to 0 °C, a solution of the crude before mentioned (766 mg, 1.5 mmol) in anhydrous THF (10 mL) was added dropwise. The reaction mixture was refluxed for 1 h before being cooled down to 0 °C. An ice cold HCl 10% solution (45 mL) was slowly added and the aqueous layer was extracted with CH₂Cl₂ (3 x 100 mL). The combined organic layer was washed with brine (100 mL), dried over Na₂SO₄ and the solvent was removed in vacuo. The crude was purified by column chromatography (pentane 100%) to afford **106** as a white solid; yield: 229 mg (31%); m.p. 68.4–71.5 °C; *R*_f = 0.45 (pentane 100%).

IR (ATR, neat): 2923s, 2852s, 2671w, 2359w, 1459m, 1364w, 1163w, 840w, 755s, 655w cm⁻¹.

1,5-Bifunctional Organomagnesium Reagent for the Ester to Acridinium Transformation

To a suspension of magnesium turnings (13.6 mg, 560 μmol) in anhydrous THF (0.20 mL) at 60 °C was added a solution of 2-bromo-*N*-(2 bromophenyl)-*N*-methylaniline (**126**) (47.7 mg, 140 μmol) in anhydrous THF (0.60 mL). The mixture was stirred at 60 °C for 3 h during which the reaction mixture turned yellow, leading to the 1,5-bifunctional organomagnesium reagent which was used directly in the next step.

General Procedure A

To a solution of this reagent in THF (140 μmol) at 60 °C was added a solution of carboxylic acid ester (100 μmol) in anhydrous THF (1.00 mL) and the reaction mixture was stirred at the same temperature for 12 h. Aqueous HBr (1.00 mL, 8.8 molL⁻¹) was added and the solvent was removed in vacuo. The residue was dissolved in MeOH and filtered over a bed (d x h: 2 cm x 2 cm) of Amberlyst® A21 free base. The solvent was removed in vacuo, the residue was dissolved in CH₂Cl₂ and 3.0 g silica gel was added. The solvent was removed in vacuo and the residue purified by column chromatography (silica gel: 10 g, d x h: 2 cm x 7 cm) with CH₂Cl₂ 100% to CH₂Cl₂/MeOH 100:2 to 100:5 to 100:8 to yield acridinium salts **128a–b**.

9-(4-Fluorophenyl)-10-methylacridinium bromide salt (128a)

Prepared according to general procedure A using methyl 4-fluorobenzoate (15.4 mg, 100 μ mol) and the 1,5-bifunctional organomagnesium reagent to afford a yellow solid; yield: 22.8 mg (63%); m.p. 212–214 $^{\circ}$ C; R_f 0.10 ($\text{CH}_2\text{Cl}_2/\text{MeOH}$ 10:1).

IR (ATR, neat): 3377w, 3059w, 2999w, 2923w, 2848w, 1601m, 1574m, 1544, 1504m, 1482w, 1446w, 1373m, 1272w, 1217m, 1156m, 1094m, 1023m, 926w, 866w, 816w, 767s, 722m, 666m, 614m.

^1H NMR (500 MHz, CDCl_3): δ = 9.05 (d, 3J 9.2, 2H, C4H, C5H), 8.41–8.44 (m, 2H, C3H, C6H), 7.97 (dd, 3J 8.8, 4J 1.2, 2H, C1H, C8H), 7.82 (dd, 3J 8.7, 6.7, 2H, C2H, C7H), 7.47–7.50 (m, 2H, C2'H, C6'H), 7.42–7.45 (m, 2H, C3'H, C5'H), 5.34 (s, 3H, NCH_3).

*Large-scale synthesis of acridinium salts***4-Bromo- N^1,N^1 -dimethylbenzene-1,3-diamine (131)**

[CAS Reg. No.: 90555-68-3]

Prepared according to a modified literature procedure.^[215,216] To a solution of 4-bromo- N,N -dimethylaniline (50.0 g, 250 mmol) in TBME/THF (1 : 1, 340 mL) was added dropwise aq. nitric

acid (68%, 16.5 mL). The mixture was stirred for 1 h at room temperature. The formed precipitate was filtered off and the residue was washed with TBME (2 x 30 mL) and dried under vacuum overnight.¹¹ The yellow salt (35.0 g, 133 mmol) was then dissolved in CH₂Cl₂ (210 mL) and the solution was added to conc. H₂SO₄ (58.0 mL) while maintaining the temperature below 5 °C. The mixture was allowed to warm up to room temperature and was stirred for 1 h. The mixture was then slowly added to cold water (210 mL) and aq. NH₄OH (28%) was added until the mixture reached pH 10. The aq. residue was extracted with DCM (2 x 500 mL), the combined organic layers were dried over Na₂SO₄ and concentrated in vacuo to obtain 4-bromo-*N,N*-dimethyl-3-nitroaniline as an orange solid; yield: 32.0 g (52%); m.p. 90.4–91.9 °C; *R*_f 0.73 (CH₂Cl₂ 100%).

IR (ATR, neat): 2920w, 1609m, 1530s, 1443w, 1369m, 1234w, 1190w, 1129w, 1069w, 881w, 679w.

¹H NMR (500 MHz, CDCl₃): δ = 7.46 (d, ³*J* 9.0, 1H, C5H), 7.07 (d, ⁴*J* 3.1, 1H, C2H), 6.69 (dd, ³*J* 9.1, ⁴*J* 3.1, 1H, C6H), 3.00 (s, 6H, N(CH₃)₂).

¹³C NMR (125 MHz, CDCl₃): δ = 150.4 (C3), 149.7 (C1), 134.9 (C5), 116.4 (C6), 108.3 (C2), 98.6 (C4), 40.3 (N(CH₃)₂).

HRMS (ESI): *m/z* calcd. for C₈H₁₀BrN₂O₂⁺ 244.9920 found 244.9921 [M+H⁺].

In agreement with literature data.^[216]

Prepared according to a modified literature procedure.^[217] To a solution of 4-bromo-*N,N*-dimethyl-3-nitroaniline (36.8 g, 150 mmol) in methanol/water (1 : 1, 430 mL), was added ammonium chloride (64.2 g, 1200 mmol) and iron powder (41.9 g, 750 mmol). The reaction mixture was stirred for 1 h at 70 °C, filtered over celite and concentrated to remove methanol.¹² The aq. residue was treated with aq. HCl (10%) and washed with diethylether (2 x 500 mL). Then, aq. NH₄OH (28%) was added until the residue reached basic pH. The aq. residue was extracted with CH₂Cl₂ (3 x 1 L). The combined organic layers were washed with brine, dried over Na₂SO₄ and concentrated in vacuo to yield 4-bromo-*N*¹,*N*¹-dimethylbenzene-1,3-diamine as a black solid; yield: 28.1 g (87%); m.p. 57.1–58.7 °C; *R*_f 0.29 (CH₂Cl₂ 100%).

¹¹ The precipitate was slowly formed after the addition of nitric acid and can be either grey or yellow (it will turn eventually yellow after drying under vacuum).

¹² The Celite was washed with EtOAc.

IR (ATR, neat): 3460w, 3355w, 2956w, 2843w, 2794w, 1604s, 1568s, 1491m, 1350m, 1291m, 1153m, 1123m, 1057w, 972w, 893w, 817s, 778s, 710w.

¹H NMR (500 MHz, CDCl₃): δ = 7.20 (d, ³J 8.8, 1H, C5H), 6.12 (d, ⁴J 2.9, 1H, C2H), 6.08 (dd, ³J 8.8, ⁴J 2.9, 1H, C6H), 3.97 (br, 2H, NH₂), 2.88 (s, 6H, N(CH₃)₂).

¹³C NMR (125 MHz, CDCl₃): δ = 151.0 (C1), 144.3 (C3), 132.5 (C5), 105.2 (C6), 99.7 (C2), 97.0 (C4), 40.6 (N(CH₃)₂).

4-Bromo-3-iodo-*N,N*-dimethylaniline (133)

[CAS Reg. No.: 1291063-32-5]

Prepared according to a modified literature procedure.^[218] To a suspension of NaI (39.0 g, 260 mmol), CuI (1.24 g, 6.50 mmol), *N,N'*-dimethylethylenediamine (1.40 mL, 13.0 mmol) in 1,4-dioxane (130 mL) at RT was added 3-bromo-*N,N*-dimethylaniline (18.6 mL, 130 mmol). The reaction mixture was stirred for 22 h at 110 °C and then cooled to RT, treated with aq. NH₄OH (28%, 650 mL) and H₂O (300 mL) and was extracted with CH₂Cl₂ (3 x 1.5 L). The combined organic layers were dried over Na₂SO₄ and concentrated in vacuo to give 3-iodo-*N,N*-dimethylaniline as a brownish oil; yield: 31.3 g (97%).

¹H NMR (500 MHz, CDCl₃): δ = 7.01–7.03 (m, 2H, C4H, C6H), 6.91–6.94 (m, 1H, C5H), 6.65–6.67 (m, 1H, C2H), 2.92 (s, 6H, N(CH₃)₂).

¹³C NMR (125 MHz, CDCl₃): δ = 151.6 (C1), 130.4 (C5), 125.2 (C4), 121.1 (C6), 111.6 (C2), 95.5 (C3), 40.3 (N(CH₃)₂).

In agreement with literature data.^[216,219]

To a solution of 3-iodo-*N,N*-dimethylaniline (31.3 g, 127 mmol) in CH₂Cl₂ (200 mL) at 10 °C was added bromine (6.53 mL, 127 mmol). The reaction mixture was stirred 1 h at that

temperature.¹³ The suspension was treated with aq. sat. Na₂SO₃ (76.0 mL) and H₂O (170 mL) and was extracted with CH₂Cl₂ (3 x 350 mL). The combined organic layers were dried over Na₂SO₄ and concentrated in vacuo. The red crude solid was recrystallized from hexane/EtOAc (50 mL; 4:1) to give 4-bromo-3-iodo-*N,N*-dimethylaniline as a beige solid; yield: 23.7 g (57%).¹⁴ In agreement with literature data.^[216,219]

4-Bromo-*N*³-(2-bromo-5-(dimethylamino)phenyl)-*N*¹,*N*¹,*N*³-trimethylbenzene-1,3-diamine (137)

Prepared according to a modified literature procedure.^[208,216] To a degassed mixture of 4-bromo-3-iodo-*N,N*-dimethylaniline (55.4 g, 170 mmol), 4-bromo-*N*¹,*N*¹-dimethylbenzene-1,3-diamine (36.6 g, 170 mmol) tris(dibenzylideneacetone)dipalladium(0) (3.89 g, 4.25 mmol), 1,1'-bis(diphenylphosphino)ferrocene (4.71 g, 8.50 mmol) and sodium *t*-butoxide (24.5 g, 255.0 mmol) was added PhMe (560 mL) at RT. The reaction mixture was stirred for 14 h at 105 °C. The solution was diluted with H₂O (800 mL) and extracted with CH₂Cl₂ (3 x 2 L). The combined organic layer was dried over Na₂SO₄ and concentrated in vacuo. The crude was purified by column chromatography on silica gel (pentane/CH₂Cl₂ 3:1 to 2:1 to 1:1) giving 4-bromo-*N*³-(2-bromo-5-(dimethylamino)phenyl)-*N*¹,*N*¹-dimethylbenzene-1,3-diamine as a beige solid; yield: 48.9 g (70%); m.p. 132.2–134.7 °C; *R*_f 0.53 CH₂Cl₂ (100%).

IR (ATR, neat): 3399w, 2895w, 2804w, 1590m, 1562s, 1496s, 1441m, 1354s, 1284s, 1230w, 1161m, 1065w, 989w, 921w, 814m, 770s, 737w, 682w.

¹H NMR (500 MHz, CDCl₃): δ = 7.36 (d, ³*J* 8.7, 2H, C3H), 6.76 (d, ⁴*J* 2.9, 2H, C6H), 6.32 (br, 1H, NH), 6.24 (dd, ³*J* 8.7, ⁴*J* 3.0, 2H, C4H) 2.89 (s, 12H, N(CH₃)₂).

¹³C NMR (125 MHz, CDCl₃): δ = 150.5 (C5), 140.3 (C1), 133.0 (C3), 107.3 (C4), 102.1 (C6), 100.8 (C2), 40.7 (N(CH₃)₂).

HRMS (ESI): *m/z* calcd. for C₁₆H₂₀Br₂N₃⁺ 412.0018 found 412.0019 [M+H⁺].

¹³ The reaction mixture turns beige immediately and the color remains until the end of the reaction.

¹⁴ After heating up to 80 °C, a hot filtration allowed to remove insoluble red solids, while the precipitated product could be isolated at RT.

In agreement with literature data.^[216]

Prepared according to a modified literature procedure.^[214,216] To a solution of 4-bromo-*N*³-(2-bromo-5-(dimethylamino)phenyl)-*N*¹,*N*¹-dimethyl-benzene-1,3-diamine (48.3 g, 117.0 mmol) in THF (334 mL) at RT was added sodium hydride (60% dispersion in mineral oil, 14.0 g, 351.0 mmol). The suspension was heated to 75 °C and stirred for 30 min at this temperature. Iodomethane (7.28 mL, 117.0 mmol) was added within 5 min at 75 °C and the reaction mixture was stirred for 2 h at this temperature. The suspension was treated with water (585 mL) and extracted with CH₂Cl₂ (3 x 1.5 L). The combined organic layers were dried over Na₂SO₄ and concentrated in vacuo. The crude solid was recrystallized from hexane/EtOAc (70 mL; 4:1) to give 4-bromo-*N*³-(2-bromo-5-(dimethylamino)phenyl)-*N*¹,*N*¹,*N*³-trimethylbenzene-1,3-diamine as a beige solid; yield: 35.6 g (71%); m.p. 102.5–104.1 °C; *R*_f 0.55 (CH₂Cl₂ 100%).

IR (ATR, neat): 2883w, 2806w, 1588s, 1554s, 1492s, 1446m, 1358s, 1304m, 1233m, 1170s, 1133m, 1084m, 1022w, 987m, 909w, 801m, 735w.

General Procedure B

To a suspension of magnesium turnings (1.36 g, 56.0 mmol) in anhydrous THF (20.0 mL) at 60 °C was added a solution of 4-bromo-*N*³-(2-bromo-5-(dimethylamino)phenyl)-*N*¹,*N*¹,*N*³-trimethylbenzene-1,3-diamine (5.98 g, 14.0 mmol) in anhydrous THF (60 mL) followed by 1,2-dibromoethane (0.319 mL, 4.20 mmol). The mixture was stirred at 60 °C for 3 h during which the reaction mixture turned yellow. To this solution at 60 °C was added a solution of carboxylic acid ester (10.0 mmol) in anhydrous THF (100 mL) and the reaction mixture was stirred at the same temperature for 12 h. Aqueous HBr (100 mL, 8.8 mol/L) was added and the aq. phase extracted with CHCl₃/*i*-PrOH (3 x 200 mL; 85:15). The solvent was removed in vacuo and the residue was recrystallized from water (10 mL) to yield acridinium salts **129a–b**.

3,6-Bis(dimethylamino)-9-mesityl-10-methylacridinium bromide salt (129a)

Prepared according to general procedure B using methyl 2,4,6 trimethyl benzoate (1.78 g, 10 mmol) to afford an orange solid; yield: 3.9 g (82%); decomp. at 192.9 °C; R_f 0.13 ($\text{CH}_2\text{Cl}_2/\text{MeOH}$ 10:1).

IR (ATR, neat): 3373w, 2918w, 2170w, 1591s, 1497s, 1435m, 1352s, 1210s, 1148s, 985w, 921s, 807m, 711s.

^1H NMR (500 MHz, CDCl_3): δ = 7.26 (d, 3J 9.5, 2H, C1H, C8H), 7.06 (br, 2H, C3'H, C5'H), 6.95–6.96 (m, 2H, C4H, C5H), 6.94 (dd, 3J 9.4, 4J 2.1, 2H, C2H, C7H), 4.56 (s, 3H, NCH₃), 3.36 (s, 12H, 2 x N(CH₃)₂), 2.43 (s, 3H, CH₃) 1.80 (s, 6H, 2 x CH₃).

Modular synthesis of acridinium salts

Overview of the synthesis

2-Bromo-*N*-(3-methoxyphenyl)-*N*-methylaniline (139a):

To a degassed mixture of tris(dibenzylideneacetone)dipalladium(0) (916 mg, 1.00 mmol), 1,1'-ferrocenediyl-bis(diphenylphosphine) (1.11 g, 2.00 mmol) and sodium *tert*-butoxide (5.77 g, 60.0 mmol) in toluene (50 mL) at RT was added *m*-anisidine **138** (4.48 mL, 40.0 mmol) and 1-bromo-2-iodobenzene **125** (5.14 mL, 40.0 mmol). The mixture was stirred at 110 °C for 12 h, then cooled to RT, diluted with water (400 mL), extracted with CH₂Cl₂ (4 x 500 mL) and dried over Na₂SO₄ and concentrated in vacuo. The crude was purified by column chromatography on silica gel (pentane/CH₂Cl₂ 1:1 to 1:2) to give 2-bromo-*N*-(3-methoxyphenyl)aniline as a yellowish oil; yield: 5.40 g (73%); *R*_f = 0.53 (CH₂Cl₂ 100%).

IR (ATR, neat): 3395w, 2955w, 2833w, 1583s, 1512m, 1491s, 1467s, 1450m, 1306m, 1273m, 1196m, 1155s, 1042m, 1021m, 960w, 840w, 740s, 688m.

¹H NMR (500 MHz, CDCl₃) δ = 7.52 (1H, dd, ³*J* 8.0, ⁴*J* 1.5, C3H), 7.29 (1H, dd, ³*J* 8.2, ⁴*J* 1.6, C6H), 7.19–7.14 (1H, m, C5'H), 7.15–7.18 (1H, m, C5H), 6.72–6.76 (2H, m, C4H, C6'H), 6.70–6.71 (1H, m, C2'H), 6.58 (1H, ddd, ³*J* 8.3, ⁴*J* 2.5, 0.8, C4'H), 6.06 (1H, br, NH), 3.79 (3H, s, OCH₃).

¹³C NMR (125 MHz, CDCl₃) δ = 143.0 (C1'), 141.1 (C1), 133.0 (C3), 130.2 (C5'), 128.1 (C3), 121.2 (C4), 116.5 (C6), 112.5 (C2), 112.4 (C6'), 108.0 (C4'), 105.7 (C2'), 55.3 (OCH₃).

HRMS (ESI): *m/z* [M+H⁺] calcd. for C₁₃H₁₃BrNO⁺: 278.0175; found: 278.0176.

To a solution of 2-bromo-*N*-(3-methoxyphenyl)aniline (3.89 g, 14.0 mmol) in THF (40 mL) at RT was added sodium hydride (60% dispersion in mineral oil, 1.68 g, 42.0 mmol). The suspension was heated to 75 °C and stirred for 30 min at this temperature. Iodomethane (0.872 mL, 14.0 mmol) was added within 5 min at 75 °C and the reaction mixture was continued to stir for 2 h at this temperature. The suspension was treated with water (60 mL) and extracted with Et₂O (4 x 150 mL). The combined organic layer was washed with brine, dried over Na₂SO₄ and concentrated *in vacuo*. The crude was used without further purification. If purified, 2-bromo-*N*-(3-methoxyphenyl)-*N*-methylaniline **139a** is obtained as a colorless oil; *R*_f = 0.61 (pentane/CH₂Cl₂ 1:1).

3-Bromo-4-iodo-*N,N*-dimethylaniline (**143**):

Prepared according to a modified literature procedure.^[220]

To a mixture of 3-bromo-*N,N*-dimethylaniline (40.0 g, 200 mmol) and calcium carbonate (80.1 g, 800 mmol) in CH₂Cl₂:MeOH (1:4, 4 L) was added benzyltrimethylammonium dichloroiodate⁴ (76.6 g, 220 mmol) at RT. The mixture was stirred at RT for 1 h, filtered and the filtrate was concentrated in vacuo, treated with aqueous sat. Na₂SO₃ (1 L), extracted with CH₂Cl₂ (3 x 2L), dried over Na₂SO₄ and concentrated in vacuo to afford 3-bromo-4-iodo-*N,N*-dimethylaniline as a brown solid. The crude was filtered through a plug of silica gel (pentane/CH₂Cl₂ 1:1), followed by recrystallization from *i*-PrOH (90 mL) to afford 3-bromo-4-iodo-*N,N*-dimethylaniline **143** as a yellowish solid; yield: 62.3 g (96%); m.p. 76.8–78.6 °C; *R*_f = 0.86 (pentane/CH₂Cl₂ 1:1).

IR (ATR, neat): 3082w, 2890m, 2814m, 1581s, 1496s, 1439s, 1365m, 1231s, 1177m, 1107m, 1066m, 981m, 956m, 825m, 793s, 664m.

¹H NMR (500 MHz, CDCl₃) δ = 7.56 (1H, d, ³J 9.2, C5H), 6.96 (1H, d, ⁴J 2.9, C2H), 6.37 (1H, dd, ³J 8.9, ⁴J 2.9, C6H), 2.92 (12H, s, N(CH₃)₂).

¹³C NMR (125 MHz, CDCl₃) δ = 151.2 (C1), 139.8 (C5), 130.1 (C3), 116.3 (C2), 113.2 (C6), 83.0 (C4), 40.2 (N(CH₃)₂); ESI-MS: m/z [M+H⁺] calcd. for C₈H₁₀BrIN⁺: 325.9036; found: 325.9032.

2-Bromo-*N*¹-(3-methoxyphenyl)-*N*⁴,*N*⁴-dimethyl-*N*¹-phenylbenzene-1,4-diamine (139e):

To a degassed mixture of tris(dibenzylideneacetone)dipalladium(0) (137 mg, 150 μ mol), 2-dicyclohexylphosphino-2',6'-diisopropoxybiphenyl (140 mg, 300 μ mol), sodium *tert*-butoxide (865 mg, 9 mmol), 3-methoxy-*N*-phenylaniline (1.20 g, 6.00 mmol) and 4-bromo-3-iodo-*N,N*-dimethylaniline (2.35 g, 7.20 mmol) was added toluene (12 mL) at RT. The mixture was stirred at 90 °C for 11 h, then cooled to RT, diluted with water (60 mL), extracted with CH₂Cl₂ (3 x 120 mL), dried over Na₂SO₄ and concentrated in vacuo. The crude was purified by column chromatography on silica gel (pentane/CH₂Cl₂ 2:1 to 1:1) to obtain **139e** as a yellow oil; yield: 1.08 g (45%) R_f = 0.63 (pentane/CH₂Cl₂ 1:1).

IR (ATR, neat): 2935w, 1588s, 1488s, 1443m, 1313m, 1272m, 1225s, 1151s, 1050m, 957m, 907s, 831m, 728s, 691s, 628w.

¹H NMR (500 MHz, CDCl₃) δ = 7.19–7.22 (2H, m, C3''H, C5''H), 7.11 (1H, d, ³J 8.8, C6H), 7.10 (1H, t, ³J 8.1, C5'H), 7.02–7.04 (2H, m, C2''H, C6''H), 6.95 (1H, d, ⁴J 2.9, C3H), 6.90–6.93 (1H, m, C4''H), 6.66 (1H, dd, ³J 8.8, ⁴J 2.9, C5H), 6.54 (1H, t, ⁴J 2.3, C2'H), 6.56 (1H, ddd, ³J 8.1, ⁴J 2.2, 0.8, C6'H), 6.46 (1H, ddd, ³J 8.2, ⁴J 2.4, 0.8, C4'H), 3.71 (3H, s, OCH₃), 2.96 (6H, s, N(CH₃)₂).

HRMS (ESI): m/z [M⁺⁺] calcd. for C₂₁H₂₁BrN₂O⁺⁺: 396.0832; found: 396.0827.

General procedure C:

To a solution of tertiary amine **139a-e** (19.8 mmol) in Et₂O (24 mL) and *n*-hexane (247 mL) was added a solution of *n*-butyllithium in hexanes (24.8 mL, 1.60 molL⁻¹, 39.6 mmol) at RT. The mixture was stirred for 6 h at 65 °C. The reaction mixture was directly used in the next step.

General procedure D:

To the reaction mixture of the metalated aryl aniline in *n*-hexane/Et₂O (271 mL) at -20 °C was added a solution of carboxylic acid ester (23.8 mmol) in anhydrous THF (100 mL) and the reaction mixture was allowed to warm to RT over 12 h. Aqueous HBr (238 mL, 48%) was added, followed by water (1 L) and the mixture was extracted by CHCl₃/*i*-PrOH solution (4 × 1 L; 85:15). The combined organic layer was dried over Na₂SO₄, filtered and concentrated in vacuo. The crude was triturated in THF (5 mL) and filtered to afford the product.

9-(2,6-Dimethylphenyl)-1-methoxy-10-phenylacridinium bromide salt (144a)

The compound was prepared according to the general procedures **C** and **D**, using 2-bromo-*N*-(3-methoxyphenyl)-*N*-phenylaniline **139b** (7.01 g, 19.8 mmol) and methyl 2,6-dimethylbenzoate (3.90 g, 23.8 mmol). Purification gave a brown red solid; yield: 4.37 g (57%); m.p. at 139 °C (decomp.); *R*_f = 0.14 (CH₂Cl₂/MeOH 10:1)

IR (ATR, neat): 3013w, 2361w, 1606m, 1582m, 1517m, 1466s, 1366m, 1271s, 1243m, 1197w, 1087s, 1030w, 977w, 771s, 738m, 701m, 670w, 626w cm⁻¹.

*Synthesis of a new generation of acridinium salts***9-(4-Bromo-3-iodophenyl)-9H-carbazole (154)**

Prepared according to a modified literature procedure.^[221]

To a mixture of carbazole **155** (3.34 g, 20 mmol) and cesium carbonate (26.1 g, 80.0 mmol) in DMF (80 mL) was added 2-*t*-Bu-aniline (0.94 mL, 6.03 mmol) was added 1-bromo-4-fluoro-2-iodobenzene **156** (10.5 mL, 80.0 mmol) and the reaction mixture was heated for 24 h at 150 °C. Brine (600 mL) was added and the aqueous layer was extracted with CH₂Cl₂ (3 x 600 mL), the combined organic layer was dried over Na₂SO₄ and the solvent was removed in vacuo. The crude was purified by column chromatography (Pentane/CH₂Cl₂ 50:1 to 10:1) to afford **154** as a white solid; yield: 2.52 g (28%); m.p. 102.0–142.4 °C; *R*_f = 0.63 (pentane/CH₂Cl₂ 10:1).

IR (ATR, neat): 3589w, 3056w, 2922s, 2833m, 2361s, 1909w, 1747w, 1596w, 1453s, 1336m, 1230s, 1177m, 1011m, 819m, 749s cm⁻¹.

¹H NMR (500 MHz, CDCl₃): δ = 8.13 (d, ³J = 7.6 Hz, 2 H, C4'*H*x2), 8.08 (d, ³J = 2.3 Hz, 1 H, C2*H*), 7.83 (d, ³J = 8.5 Hz, 1 H, C5*H*), 7.45 (d, ³J = 8.5 Hz, 1 H, C6*H*), 7.44 (t, ³J = 8.1 Hz, 2 H, C2'*H*x2), 7.38 (d, ³J = 7.8 Hz, 2 H, C1'*H*x2), 7.31 (t, ³J = 8.1 Hz, 2 H, C3'*H*x2).

¹³C NMR (125 MHz, CDCl₃): δ = 140.4 (C1'*a*), 138.5 (C2), 137.5 (C1), 133.6 (C5), 128.4 (C4), 128.1 (C6) 126.3 (C2'), 123.6 (C4'*a*), 120.6 (C3'), 120.5 (C4'), 109.5 (C1'), 102.0 (C3).

HRMS (ESI): *m/z* [M + H⁺] calcd. for C₁₈H₁₂F₃NBrI⁺: 447.9192; found: 447.9189.

2-Bromo-5-(9*H*-carbazol-9-yl)-*N*-phenylaniline (153a)

To a degassed mixture of **154** (269 mg, 0.60 mmol), tris(dibenzylideneacetone)dipalladium(0) (13.7 mg, 15.0 μmol), 1,1'-bis(diphenylphosphino)ferrocene (16.6 mg, 30.0 μmol) and sodium *t*-butoxide (86.5 mg, 0.90 mmol) was added aniline (0.05 mL, 0.60 mmol) and toluene (2 mL) at RT. The reaction mixture was stirred for 14 h at 105 °C. The solution was diluted with H₂O (3 mL) and extracted with CH₂Cl₂ (3 x 6 mL). The combined organic layer was dried over Na₂SO₄ and concentrated in vacuo. The crude was purified by column chromatography on silica gel (pentane/CH₂Cl₂ 100:1) giving **153a** as a white solid; yield: 234 mg (94%); m.p. 140.6–154.6 °C; *R*_f 0.42 (pentane/CH₂Cl₂ 10:1)

IR (ATR, neat): 3401w, 2925w, 2362s, 1554m, 1501m, 1451m, 1312w, 1227m, 1167w, 1027w, 940w, 808s, 750w cm⁻¹.

3,6-Di(9*H*-carbazol-9-yl)-9-mesityl-10-phenylacridin-10-ium bromide (152**):**

To a suspension of magnesium turnings (27.2 mg, 1.12 mmol) in a mixture of anhydrous THF (0.4 mL) at 60 °C was added a solution of **153** (205 mg, 0.28 mmol) in a mixture of anhydrous Me-THF and toluene 1:1 (1.2 mL) followed by 1,2-dibromoethane (6.00 μ L, 84.0 μ mol). The mixture was stirred at 60 °C for 3 h during which the reaction mixture turned yellow. To this solution at 60 °C was added a solution of mesityl methyl ester (35.6 mg, 0.20 mmol) in anhydrous THF (1 mL) and the reaction mixture was stirred at the same temperature for 12 h. Aqueous HBr (1 mL, 8.8 molL⁻¹) was added and the aq. phase extracted with CHCl₃/*i*-PrOH (3 x 2 mL; 85:15). The solvent was removed in vacuo and the residue was triturated in Et₂O (1 mL) giving **152** as a purple solid; yield: 49 mg (31%); decomp. at 350 °C; *R*_f 0.32 (CH₂Cl₂/MeOH 10:1).

IR (ATR, neat): 3727w, 3057w, 2925w, 2361s, 1599s, 1452s, 1331s, 1227m, 1131w, 930w, 818s, 771s, 722s, 645s cm⁻¹.

¹H NMR (500 MHz, MeOD): δ = 8.27 (dd, ³*J* = 9.4 Hz, ⁴*J* = 2 Hz, 2 H, C2*H*, C7*H*), 8.17 (d, ³*J* = 9.4 Hz, 2 H, C1*H*, C8*H*), 8.12 (d, ³*J* = 7.8 Hz, 4 H, C4'*H*x4), 8.07 (d, ³*J* = 7.4 Hz, 2 H, C2''*H*x2), 7.92 (dd, ³*J* = 7.4 Hz, ³*J* = 7.7 Hz, 2 H, C3''*H*x2), 7.79 (t, ³*J* = 7.7 Hz, 1 H, C4''*H*), 7.70 (d, ⁴*J* = 2 Hz, 2 H, C4*H*, C5*H*), 7.66 (d, ³*J* = 8.3 Hz, 4 H, C1'*H*x4), 7.42 (dd, ³*J* = 8.3 Hz, ³*J* = 1.5 Hz, 4 H, C2'*H*x4), 7.36–7.33 (m, 6 H, C3''*H*x2, C3'*H*x4), 2.55 (s, 3H, CH₃), 2.09 (s, 6H, CH₃x2).

¹³C NMR (125 MHz, MeOD): δ = 163.5 (C9), 148.4 (C4a), 145.3 (C3), 142.0 (C4'''), 140.3 (C1'a), 138.7 (C1''), 137.7 (C1'''), 132.7 (C1, C3''), 130.5 (C2'''), 130.2 (C3'''), 129.6 (C2''), 128.0 (C2'), 127.3 (C2), 126.4 (C4'a), 125.4 (C9a), 123.8 (C3'), 121.8 (C4'), 114.6 (C4), 111.2 (C1'), 21.4 (CH₃), 20.3 (CH₃x2).

4-Bromo-1-chloro-2-iodobenzene (183)

[CAS Reg. No.: 774608-49-0]

To a suspension of 5-bromo-2-chloroaniline **184** (10.3 g, 50.0 mmol) in HCl 37% (10 mL) and water 50 mL at 0 °C was added a solution of sodium nitrite (4.14 g, 60.0 mmol) in water (20 mL) over 5 min. The dark red brown mixture was stirred at 0 °C for 45 min and was added to a solution of potassium iodide (16.6 g, 100 mmol) in water (100 mL) at 0 °C. The reaction mixture was stirred at 0 °C for 30 min and at RT for 2 h. The reaction was extracted with Et₂O (3x1000 mL) and the organic phase was washed with 2M HCl (3x750 mL), NaHCO₃ (2x500 mL) and brine (1000 mL). The organic phase was dried over Na₂SO₄ and the solvent removed in vacuo. The crude mixture was used without further purification.

The spectral data were in agreement with literature data.^[222]

Bis(5-bromo-2-chlorophenyl)amine (182)

To a degassed mixture of 4-bromo-1-chloro-2-iodobenzene **183** (635 mg, 2.00 mmol), 5-bromo-2-chloro-aniline **184** (413 mg, 2.00 mmol), tris(dibenzylideneacetone)dipalladium(0) (45.8 mg, 0.05 mmol), 1,1'-bis(diphenylphosphino)ferrocene (55.4 mg, 0.10 mmol) and sodium *t*-butoxide (288 mg, 3.00 mmol) was added toluene (6 mL) at RT. The reaction mixture was stirred for 1 h at 105 °C. The solution was diluted with H₂O (8 mL) and extracted with CH₂Cl₂ (3 x 15 mL). The combined organic layer was dried over Na₂SO₄ and concentrated in vacuo. The crude was purified by column chromatography on silica gel (pentane/CH₂Cl₂ 100:1) giving **182** as a white solid; yield: 698 mg (88%); m.p. 114.5–127.9 °C; R_f 0.67 (pentane/CH₂Cl₂ 10:1).

IR (ATR, neat): 1588m, 1512m, 1313w, 1046w, 918w, 869w, 803w, 642s, 620s cm⁻¹.

***N*¹,*N*¹,*N*³-Triphenylbenzene-1,3-diamine (193)**

Prepared according to a modified literature procedure.^[223]

To a degassed mixture of 1-bromo-3-iodobenzene **191** (2.55 g, 9.00 mmol), diphenylamine **192** (1.52 g, 9.00 mmol) palladium acetate (II) (20.2 mg, 0.09 mmol), XantPhos (52.1 mg, 0.09 mmol) and sodium *t*-butoxide (2.60 g, 27.0 mmol) was added toluene (18 mL) at RT. The reaction mixture was stirred for 15 min at 110 °C. After this time, aniline (0.86 mL, 9.45 mmol) was added and the reaction mixture stirred for an additional 3 h.¹⁵ The solution was diluted with H₂O (20 mL) and extracted with CH₂Cl₂ (3 x 30 mL). The combined organic layer was dried over Na₂SO₄ and concentrated in vacuo. The crude was dissolved in CH₂Cl₂, filtered through a plug of silica and was used without any further purification.

4-Bromo-*N*¹,*N*¹,*N*³-triphenylbenzene-1,3-diamine (**194**)

Prepared according to a modified literature procedure.^[224]

To a solution of **193** (3.03 g, 9.00 mmol) in CH₂Cl₂ (80 mL) at 0 °C was added NBS (1.60 g, 9.00 mmol) and the reaction mixture stirred at this temperature for 1 h. The solution was diluted with H₂O (100 mL) and extracted with CH₂Cl₂ (3 x 150 mL). The combined organic layer was dried over Na₂SO₄ and concentrated in vacuo. The crude was submitted to a column chromatography on silica gel (Cyclohexane/EtOAc 200:1) followed by recrystallizations in (MeOH, EtOH, H₂O) however the product could not be purified and was used as is in the next reaction.

¹⁵ If a full conversion is not achieved after 3 h, Pd₂dba₃ (5 mol%) along with dppf (10 mol%) can be added to drive the reaction to completion.

**General procedure E:**

To a solution of tertiary amine **196** (1.40 mmol) in Et₂O (1.7 mL) and *n*-hexane (17 mL) was added a solution of *n*-butyllithium in hexanes (1.75 mL, 1.60 molL⁻¹, 2.80 mmol) at RT. The mixture was stirred for 5 h at 65 °C. The reaction mixture was directly used in the next step.

General procedure F:

To the reaction mixture of the metalated aryl aniline in *n*-hexane/Et₂O (18.7 mL) at -20 °C was added a solution of carboxylic acid ester (1.00 mmol) in anhydrous THF (3.6 mL) and the reaction mixture was allowed to warm to RT over 12 h. Aqueous HBr (9 mL, 48%) was added, followed by water (40 mL) and the mixture was extracted by CHCl₃/*i*-PrOH solution (4 × 80 mL; 85:15). The combined organic layer was dried over Na₂SO₄, filtered and concentrated in vacuo. The crude was purified by column chromatography on silica gel (CH₂Cl₂/MeOH 100:0.5 to 100:5) affording acridinium salts **197a-d**.

9-(2,6-Dimethylphenyl)-6-(diphenylamino)-1-methoxy-10-phenylacridin-10-ium bromide salt (197a)

The compound was prepared according to the general procedures **E** and **F**, using 4-bromo- N^1,N^1,N^3 -triphenylbenzene-1,3-diamine **194** (730 mg, 1.40 mmol) and methyl 2,6-dimethylbenzoate (164 mg, 1.00 mmol). Purification gave a black red solid; yield: 239 mg (42%); decomp. > 350 °C; R_f = 0.61 ($\text{CH}_2\text{Cl}_2/\text{MeOH}$ 10:1).

4.2.3 Photoredox catalysis

Photocatalyzed deuteration**General procedure G:**

According to a modified literature procedure.^[200] To a mixture of triisopropylsilanethiol (5.71 mg, 30 μ mol), lithium carbonate (35.5 mg, 480 μ mol), photocatalyst (2.5 mol%, see table below) and deuterium oxide (90.0 μ L, 5.00 mmol) in *N*-methylpyrrolidone (1.6 mL) was added clomipramine hydrochloride (33.7 mg, 100 μ mol) and was degassed by a stream of argon for 20 min. The reaction was performed under argon atmosphere for 24 h with the light on. The reaction mixture was diluted in EtOAc (15 mL), washed with brine (20 mL) and extracted with EtOAc (3 x 15 mL). The combined organic layer was concentrated in vacuo and column chromatographed on silica gel with *n*-hexane:acetone:Et₃N, 96:2:2 to afford clomipramine free base. *R_f* 0.34 (*n*-hexane:acetone:Et₃N, 8:1:1); clomipramine free base (deuterated using **144b** as photocatalyst).

¹H NMR (500 MHz, MeOD): δ = 7.12–7.17 (m, 3H), 7.09–7.10 (m, 1H), 7.02–7.03 (m, 1H), 6.95–6.98 (m, 1H), 6.85–6.87 (m, 1H), 3.73–3.76 (m, 1.75H, 12% 2H, C1'*H*), 3.07–3.15 (m, 4H, C5*H*, C6*H*), 2.33–2.40 (m, 1.03H, 49% 2H, C3'*H*), 2.11–2.15 (m, 4.16H, 30% 2H, N(CH₃)₂), 1.70–1.74 (m, 2H, C2'*H*).

In agreement with literature.^[200]

To afford the clomipramine HCl salt, the free base was dissolved in EtOAc, treated with HCl in dioxane (4 molL⁻¹, 250 μ L), concentrated in vacuo, triturated from Et₂O and filtered.

[a] Reaction performed with clomipramine HCl (100 μ mol), Li₂CO₃ (480 μ mol), triisopropylsilanethiol (30 mol%), photocat. (2.5 mol%), unless stated otherwise, D₂O (5.00 mmol) in NMP (1.6 mL) at RT, 24 h irradiation with Kessil A160WE tuna blue; [b] Yield of isolated products;

[c] Determined by ¹H NMR of the free base; [d] Using 1 mol% of photocatalyst.

Photoisomerization of trans-stilbene**General procedure H:**

A solution of *trans*-stilbene (10 mM) and **Photocatalyst** (0.1 mM) in 3.0 mL CD₃CN was deoxygenated with argon for five minutes in a cuvette equipped with septum cap. The reaction mixture was irradiated with light at room temperature under air cooling for 2 h. Conversion of *trans*- to *cis*-stilbene was monitored by ¹H NMR spectroscopy. *Cis*-stilbene, whose NMR data are in agreement with those presented in ref.^[225], is the only detectable product produced upon illumination.

6 APPENDIX

6.1 HPLC data

(rac) Methyl (R)-2-chloro-2-fluoro-3-phenylpropanoate (25)

No.	Ret.Time min	Height mAU	Area mAU*min	Rel.Area %	Amount n.a.	Type
1	11,95	1184,486	315,331	49,82	n.a.	BMB*
2	23,62	603,651	317,602	50,18	n.a.	BMB*
Total:		1788,137	632,933	100,00	0,000	

Analyzed on a Chiralpak® OJ-H column using a 1.0 mL/min flow of *n*-heptane/i PrOH 90:10.

Methyl (R)-2-chloro-2-fluoro-3-phenylpropanoate (25)

No.	Ret.Time min	Height mAU	Area mAU*min	Rel.Area %	Amount n.a.	Type
1	12,00	610,742	149,182	54,32	n.a.	BMB*
2	23,72	256,027	125,465	45,68	n.a.	BMB*
Total:		866,769	274,647	100,00	0,000	

Analyzed on a Chiralpak® OJ-H column using a 1.0 mL/min flow of *n*-heptane/i PrOH 90:10.

(rac)-N-(2-(*tert*-butyl)phenyl)-3-(hydroxymethyl)-N-methylphenanthrene-4-carboxamide
(96)

No.	Ret.Time min	Height mAU	Area mAU*min	Rel.Area %	Amount n.a.	Type
1	10,35	91,675	30,727	40,67	n.a.	BMB*
2	12,03	85,680	36,937	48,89	n.a.	BMB*
3	16,07	5,394	3,251	4,30	n.a.	BM *
4	17,20	5,901	4,642	6,14	n.a.	MB*
Total:		188,650	75,557	100,00	0,000	

Analyzed on a Chiralpak® IC-3 column using a 1.0 mL/min flow of *n*-heptane/*i* PrOH 70:30.

***N*-(2-(*tert*-butyl)phenyl)-3-(hydroxymethyl)-*N*-methylphenanthrene-4-carboxamide (96)**

No.	Ret.Time min	Height mAU	Area mAU*min	Rel.Area %	Amount n.a.	Type
1	10,75	82,933	31,565	82,40	n.a.	BMB*
2	12,58	7,598	3,633	9,48	n.a.	BMB*
3	17,18	3,585	2,291	5,98	n.a.	BMB*
4	20,05	0,754	0,820	2,14	n.a.	BMB*
Total:		94,871	38,308	100,00	0,000	

Analyzed on a Chiralpak® IC-3 column using a 1.0 mL/min flow of *n*-heptane/*i* PrOH 70:30.

***N*-(2-(*tert*-butyl)phenyl)-2-(hydroxymethyl)-*N*-methyl-1-naphthamide (101)**

Analyzed on a Chiralpak® OD-H column using a 1.0 mL/min flow of *n*-heptane/*i* PrOH 90:10 with the enantiopure proline tetrazole catalyst (right) and the racemic (left).

Rotational profile of 1(1,4)-naphthalenacyclohexadecaphane-1²-carbaldehyde (116)

No.	Ret.Time min	Height mAU	Area mAU*min	Rel.Area %	Amount n.a.	Type
1	7,18	1287,837	385,556	50,40	n.a.	BMB*
2	8,18	953,812	379,443	49,60	n.a.	BMB*
Total:		2241,650	764,999	100,00	0,000	

Analyzed on a Chiralpak® OD-H column using a 1.0 mL/min flow of *n*-heptane/*i* PrOH 99:1 at 0°C.

No.	Ret.Time min	Height mAU	Area mAU*min	Rel.Area %	Amount n.a.	Type
1	6,67	1003,774	345,486	50,15	n.a.	BM *
2	8,52	987,313	343,358	49,85	n.a.	MB*
Total:		1991,087	688,844	100,00	0,000	

Analyzed on a Chiralpak® OD-H column using a 1.0 mL/min flow of *n*-heptane/*i* PrOH 99:1 at 20°C.

No.	Ret.Time min	Height mAU	Area mAU*min	Rel.Area %	Amount n.a.	Type
1	6,50	1240,772	435,751	50,38	n.a.	BM *
2	8,17	1226,097	429,096	49,62	n.a.	MB*
Total:		2466,869	864,848	100,00	0,000	

Analyzed on a Chiralpak® OD-H column using a 1.0 mL/min flow of *n*-heptane/*i* PrOH 99:1 at 40°C.

6.2 NMR data

6.3 UV/VIS & Fluorescence spectra

9-(4-fluorophenyl)-10-methylacridin-10-ium bromide salt (128a)

UV/Vis Spectroscopy:

Measurement Properties
Wavelength Range (nm.): 190.00 to 800.00
Scan Speed: Medium
Sampling Interval: 1.0
Auto Sampling Interval: Disabled
Scan Mode: Single

Sample Preparation Properties

Weight: 0.788
Volume: 100 mL
Dilution: -
Path Length: 1.00 cm
Additional Information: SL-007 ACN

Instrument Properties

Instrument Type: UV-1600 Series
Measuring Mode: Absorbance
Slit Width: 2.0 nm
Light Source Change Wavelength: 340.8 nm
S/R Exchange: Normal

Attachment Properties

Attachment: None

No.	P/V	Wavelength	Abs.	Description
1		672.00	-0.059	
2		635.00	-0.062

Fluorescence Spectroscopy:

Excitation Wavelength: 500 nm

Excitation Slit Width: 5 nm

Emission Slit Width: 2 nm

Integration Time: 0.2 s

Solvent: MeCN

λ_{em} : 578 nm

FWHM: 98 nm

**(±)-7-(Dimethylamino)-1-methoxy-9-(naphthalen-1-yl)-10-phenylacridinium bromide salt
(144d)**

UV/Vis Spectroscopy:

Measurement Properties
Wavelength Range (nm.): 190.00 to 800.00
Scan Speed: Medium
Sampling Interval: 1.0
Auto Sampling Interval: Disabled
Scan Mode: Single

Sample Preparation Properties
Weight: 0.334 mg
Volume: 10 mL
Dilution: 3 fold
Path Length: 1.00 cm
Additional Information: CF1253P rac in Acetonitrile

Instrument Properties
Instrument Type: UV-1600 Series
Measuring Mode: Absorbance
Slit Width: 2.0 nm
Light Source Change Wavelength: 340.8 nm
S/R Exchange: Normal

Attachment Properties
Attachment: None
FWHM: 112 nm

6.4 Cyclic voltammetry (CV)

9-(4-fluorophenyl)-10-methylacridin-10-ium bromide salt (**128a**)

Cyclic voltammogram of acridinium dye **128a** shows a ground state reduction potential $E_{1/2}(P/P^-)$ of -0.51 V against SCE.

The excitation energy ($E_{0,0}$) of acridinium dye **128a** is 436 nm or 2.83 eV. Resulting in an excited state reduction potential $E_{1/2}(P^*/P^-)$ of +2.32 V.

9-(4-Methoxyphenyl)-10-methylacridinium bromide salt (**128b**)

Cyclic voltammogram of acridinium dye **128b** shows a ground state reduction potential $E_{1/2}(P/P^-)$ of -0.56 V against SCE.

The excitation energy ($E_{0,0}$) of acridinium dye **128a** is 447 nm or 2.77 eV. Resulting in an excited state reduction potential $E_{1/2}(P^*/P^-)$ of +2.21 V.

3,6-Bis(dimethylamino)-9-(2,6-Dimethylphenyl)-10-methylacridinium bromide salt (129b)

Cyclic voltammogram of acridinium dye **129b** shows a ground state reduction potential $E_{1/2}(P/P^-)$ of -1.15 V against SCE.

The excitation energy ($E_{0,0}$) of acridinium dye **129b** is 516 nm or 2.4 eV. Resulting in an excited state reduction potential $E_{1/2}(P^*/P^-)$ of +1.25 V.

9-(2,6-Dimethylphenyl)-1-methoxy-10-phenylacridinium bromide salt (144a)

Cyclic voltammogram of acridinium dye **144a** shows a ground state reduction potential $E_{1/2}(P/P^-)$ of -0.56 V against SCE.

The excitation energy ($E_{0,0}$) of acridinium dye **144a** is 550 nm or 2.25 eV. Resulting in an excited state reduction potential $E_{1/2}(P^*/P^-)$ of +1.69 V.

6-(Dimethylamino)-9-mesityl-1-methoxy-10-phenylacridinium bromide salt (144b)

Cyclic voltammogram of acridinium dye **144b** shows a ground state reduction potential $E_{1/2}(P/P^-)$ of -0.89 V against SCE.

The excitation energy ($E_{0,0}$) of acridinium dye **144b** is 541 nm or 2.29 eV. Resulting in an excited state reduction potential $E_{1/2}(P^*/P^-)$ of +1.40 V.

(±)-6-(Dimethylamino)-1-methoxy-9-(naphthalen-1-yl)-10-phenylacridinium bromide salt (144c)

Cyclic voltammogram of acridinium dye **144c** shows a ground state reduction potential $E_{1/2}(P/P^-)$ of -0.87 V against SCE.

The excitation energy ($E_{0,0}$) of acridinium dye **144c** is 545 nm or 2.27 eV. Resulting in an excited state reduction potential $E_{1/2}(P^*/P^-)$ of +1.40 V.

(±)-7-(Dimethylamino)-1-methoxy-9-(naphthalen-1-yl)-10-phenylacridinium bromide salt (144d)

Cyclic voltammogram of acridinium dye **144d** shows a ground state reduction potential $E_{1/2}(P/P^-)$ of -0.68 V against SCE.

The excitation energy ($E_{0,0}$) of acridinium dye **144d** is 663 nm or 1.87 eV. Resulting in an excited state reduction potential $E_{1/2}(P^*/P^-)$ of +1.19 V.

6-(Dimethylamino)-9-(2,6-dimethylphenyl)-1-methoxy-10-phenylacridinium bromide salt (144e)

Cyclic voltammogram of acridinium dye **144e** shows a ground state reduction potential $E_{1/2}(P/P^-)$ of -0.90 V against SCE.

The excitation energy ($E_{0,0}$) of acridinium dye **144e** is 541 nm or 2.29 eV. Resulting in an excited state reduction potential $E_{1/2}(P^*/P^-)$ of +1.39 V.

9-Mesityl-1-methoxy-10-phenylacridinium bromide salt (144f)

Cyclic voltammogram of acridinium dye **144f** shows a ground state reduction potential $E_{1/2}(P/P^-)$ of -0.57 V against SCE.

The excitation energy ($E_{0,0}$) of acridinium dye **144f** is 552 nm or 2.25 eV. Resulting in an excited state reduction potential $E_{1/2}(P^*/P^-)$ of $+1.68$ V.

1-Methoxy-9,10-diphenylacridinium bromide salt (144g)

Cyclic voltammogram of acridinium dye **144g** shows a ground state reduction potential $E_{1/2}(P/P^-)$ of -0.54 V against SCE.

The excitation energy ($E_{0,0}$) of acridinium dye **144g** is 555 nm or 2.23 eV. Resulting in an excited state reduction potential $E_{1/2}(P^*/P^-)$ of $+1.69$ V.

1-Methoxy-10-methyl-9-phenylacridinium bromide salt (144h)

Cyclic voltammogram of acridinium dye **144h** shows a ground state reduction potential $E_{1/2}(P/P^-)$ of -0.48 V against SCE.

The excitation energy ($E_{0,0}$) of acridinium dye **144h** is 541 nm or 2.29 eV. Resulting in an excited state reduction potential $E_{1/2}(P^*/P^-)$ of +1.81 V.

6.5 Photostability studies

Comparative stability of six acridinium dyes and $[\text{Ru}(\text{bpy})_3]^{2+}$ (Rubpy) upon illumination with a blue LED in argon-saturated acetonitrile. Main plots, UV/Vis absorption spectra measured after the illumination times given in the corresponding insets. The illuminations were stopped for 2 minutes while the absorption spectra were detected.

Abbreviations

Ac	acetyl	IR	infrared
Acr	acridinium salt	λ_{abs}	absorption maximum
Al	aliphatic	LED	light-emitting diode
Ar	aromatic	λ_{em}	Emission maximum
Aq	aqueous	LUMO	lowest unoccupied molecular orbital
BINAP	2,2'-bis(diphenylphosphino)-1,1'-binaphthyl	Me	methyl
Boc	tert-butyloxycarbonyl	MeCN	acetonitrile
bpy	2,2'-bipyridyl	MeOH	methanol
Bu	butyl	Mes	mesityl
Bn	benzyl	MS	mass spectrometry
$^{\circ}\text{C}$	degrees centigrade	N.C	no conversion
cat.	catalytic	n.d.	not determined
Cbz	carbazole	NMR	nuclear magnetic resonance
dba	dibenzylideneacetone	NOE	nuclear Overhauser effect
DMF	dimethylformamide	Ph	phenyl
DMSO	dimethylsulfoxide	Rac	racemic
dppf	1,1'-bis(diphenylphosphino)ferrocene	RT	room temperature
d. r.	Diastereomeric ratio	Ruphos	2-dicyclohexylphosphino-2',6'-diisopropoxybiphenyl
ee	enantiomeric excess	SCE	saturated calomel electrode
λ_{max}	molar absorption coefficient	SET	single electron transfer
e.r.	enantiomeric ratio	T	temperature
eV	Electronvolt	TBAI	tetrabutylammonium iodide
$E_{1/2}$	half-wave potential	DFT	density functional theory
FWHM	full width at half maximum	THF	tetrahydrofuran
h	hours	TLC	thin layer chromatography
HOMO	highest occupied molecular orbital	TTET	driplet-triplet energy transfer
HPLC	high performance liquid chromatography	UV	ultra-violet light
HRMS	high resolution mass spectrometry	V	volt
hν	photon energy, light	Xyl	xylyl

Curriculum Vitae

Bouthayna Zilate

PERSONNAL DETAILS

Date and place of birth	18 November 1988 in Casablanca (Morocco)
Nationality	French - Moroccan
Languages	Arabic (native language), French (native language), English, Spanish

ACADEMIC BACKGROUND

2016 - 2020	 PhD in Organic Chemistry - <i>University of Basel – CH-4056 Basel, SCHWEIZ</i> Supervisor : Prof. Dr. Christof Sparr
2006 - 2014	 PharmD in Industry – <i>Université de Paris V - 75006 Paris, FRANCE</i>
2012 - 2013	 Master's degree of Chemistry applied to biological science – <i>Université de Paris V - 75006 Paris, FRANCE</i> Supervisor : Prof. Dr. Hervé Galons

OTHER EXPERIENCE

2013 - 2016	 Pharmacist – <i>Pharmacie Première – 75004 Paris, FRANCE</i> <i>Pharmacie du Palais – 94400 Creteil, FRANCE</i> <i>Grande Pharmacie Wagram – 75008 Paris, FRANCE</i> <ul style="list-style-type: none">• Dispensing drugs• Clinical expertise• Customer service• Management of medicines• Management of a team
2011 - 2012	 Pharmacy Intern - <i>Centre Hospitalier National d'Ophtalmologie des XV-XX - 75012 Paris</i> <ul style="list-style-type: none">• Quality control of ophthalmic preparation• Medical prescription analysis
